Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 28, 1894.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XIV. (NEW SERIES.)

FROM JULY 6, 1894, TO DECEMBER 28, 1894.

LONDON:

Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1894.

Digitized by Google

INDEX TO VOL. XIV. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Accumulators, Commercial Efficiency of, 171
Accumulators, Commercial Possibilities of, 695, 718
Accumulators, Use of, with Motors, 238, 281
Abney, W. de W., Photometry, 95
Action of Electric Currents on Water-pipes, 32
Advertising by Aid of Electricity, 296, 472, 561, 622
Ageing Brandy Electrically, 201, 249
Agencies, 52, 197, 491, 585
Alternating-Current Plant, Rapid Development of, 113
Alternating Currents and Fuses, 606
Aluminium, Production of, by French Electro-Metallurgical Company, 2
Applications for Provisional Patents, see each Issue
Appointments, 24, 58, 69, 79, 80, 82, 137, 229, 339, 373, 436, 464, 527, 529, 530, 584, 585, 617, 649, 730, 759
Appointments Vacant, 23, 24, 51, 83, 110, 166, 197, 229, 262, 289, 339, 464, 528, 559, 617, 673, 705, 760
Amalgamation of Storage Battery Companies in America, 738
American Institute of Electrical Engineers, 345, 649
Amsterdam Hotel Exhibition, 442
An Acknowledgment (Breach of Etiquette) 377
Anarchists and Electricity, 201
And So Say All of Us (North-East Sanitary Association's Report), 169
Annual Excursion of Rashleigh Phipps and Co.'s Employes, 54
Anglo-American Cable, New, 51
Anthony, W. A., Electrical Resonance as Related to the Transmission of Energy, 38
Antwerp Exhibition, 59, 345, 413, 527, 649
"Aphrodite" Electric Launch, 276
Arc, Electric, Effect of, on Carbon, 679
Arundel Castle Installation, 111, 176, 206
Association of Chambers of Commerce, 236, 323
Association of Municipal Engineers, 57, 114, 499, 533, 566
Atlantic Telegraphy, Competition in, 348
Atmospheric Electricity, 57
Auer Lamp Lighted by Electricity, 141
Austrian Electrical Trades, Report on, 347
Automatic Control of Current Intensity, 296
Automatic Recording Instruments, 527
Automatic Telephone Exchange, 170
Automatic Variable Steam Cut-off Operated by Electricity, 35
Ayrton-Mather Galvanometer, New, 406

B.

Baker, T. W., Utilisation of Town Refuse for Generating Steam, 403
Ballets, Electric, 29, 377, 444
Bankside Accident, 379, 415
Barges, Electric Propulsion of, 522
Barnes, D. L., Electricity in Heavy Railroad Service, 282
Battersea Polytechnic, 293, 533
Bedell, F., and G. S. Moler, Optical Phase Indicator and Synchroniser, 11
Bedell, F., and C. P. Steinmetz, Reactance, 62
Bedford Electricity Works, 626, 635, 649, 677, 701
Belgian Arms Factory, Electricity at, 323
Bell, L., Some Facts about Polyphase Motors, 219, 245
Belts, "Electric," 469
Benzenberg, G. H., Electrolysis of Water-mains, 477
Berlin Exhibition, Electric Launches at, 441
Best Kept Electrical Sections, Prizes for, 414
Bidwell, S., Effect of Magnetisation upon the Dimensions of Iron Rings in Directions Perpendicular to the Magnetisation, 745
Bidwell, S., Effect of Magnetisation upon the Dimensions of Wires and Rings of Annealed Iron, 595
Binswanger, G., Electric Power, Heating, and Lighting, 125
Birkenhead Tramways, Proposed Purchase by Town Council, 289
Blackfriars Accident, 16, 29
Blackpool Accident, 589
Blackwall Entrance Lock, Opening of, 170
Blackwell, R. W., and P. Dawson, Electric Traction, with Special Reference to the Installation of Elevated Conductors, 552, 691
Bleaching by Electricity, 141
Block Telegraph, The, 681
Board of Trade and Light Railways, 525, 561, 652, 699, 711
Board of Trade Standards and Standardising Laboratory, 370, 397
Bolata, a Substitute for Indiarubber, 497
Bolton Electricity Works, 503, 516, 551
Bordeaux International Exhibition, 29, 321, 499, 562, 623, 709
Boring Machines for Mines, 2
Borough Polytechnic, 534
Bragge, R., and A. H. Lea, Special Chronograph, 186
Bramwell, Sir F., on Science, 471
Bramwell, Sir F., Some Reminiscences of Steam Locomotion on Common Roads, 161
Bridge Building, Electric Cranes for, 143
Brillie Meter, The, 1
Brine, Electrical Decomposition of, at Stafford, 110

British Association:
Continuous-Current Distribution of Electricity at High Voltage, being a Description of the Lighting of the City of Oxford, T. Parker, 178
Direct-Reading Form of Platinum Thermometer, G. M. Clark, 211
Discharge of High-Pressure Electricity through Gases, J. J. Thomson, 213
Electrolytic Methods of Quantitative Analysis, Report of Committee on, 188
Engineering Laboratory Instruments and their Calibration, D. S. Capper, 187
Fletcher, L., Address to Geological Section, 212
Hertzian Waves, Prof. Lodge, 212
Hunting of Governed Engines, J. Swinburne, 191
Kennedy, Prof., Address to Mechanical Science Section, 157
Lighthouse Apparatus and Lighthouse Administration in 1894, J. Kenward, 188
Notice of Meeting, 113
On the Construction of Delicate Galvanometers, Prof. Schuster, 186
Preliminary Experiments for Comparing the Discharge of a Leyden Jar through Different Branches of a Divided Channel, Lord Kelvin and A. Galt, 185
Preliminary Experiments to find if Subtraction of Water from Air Electrifies it, Lord Kelvin, M. Maclean, and A. Galt, 186
Presidential Address, Lord Salisbury, 145
Report of the Electrical Standards Committee, 221
Rucker, Prof., Address to Mathematical and Physical Section, 149
Signalling through Space, W. H. Preece, 188
Some Advantages of Alternate Currents, Prof. Thompson, 180
Some Reminiscences of Steam Locomotion on Common Roads, Sir F. Bramwell, 161
Special Chronograph, A. H. Lea and R. Bragge, 186
The Most Economical Temperature for Steam-engine Cylinders, or Hot *v.* Cold Walls, B. Donkin, 187

British Insulated Wire Company's Cables and the City Lighting, 535
Brown Alternating-Current Motor, Tests of, 2
Brussels Electric Tramways, 208
Business Changes, etc., 24, 79, 262, 491, 645

C.

Cable Companies and the Chinese-Japanese War, 413
Cable Interruptions and Repairs, 7

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XIV. LONDON, JULY 6, 1894. PRICE 3D.

NOTES.

Hawarden.—A 15,000-c.p. arc lamp, to be erected on the Heights, is to astonish the natives.

Central London Railway.—The Royal assent has been given to the Central London (Extension of Time) Bill.

The Cape.—Mr. Cecil Rhodes has announced that the overland telegraph wire will be open to Blantyre in October.

Central Station at Stuttgart.—Messrs. Schuckert and Co. have obtained the contract for this central electric light station.

Telephony in Switzerland.—Telephonic communication has been established between St. Gall and Appenzell. Another line joins Appenzell with Weissbad and Schwendi.

Wiener Privat-Telegraphen-Gesellschaft.—A dividend of 5 per cent. for the past year is declared by the directors. For the previous year the dividend was 3 per cent.

Electricity at Baden-by-Vienna.—In this watering place the streets were lighted electrically for the first time on the 23rd ult. An electric tramway has also been opened.

Hamburg Traction.—Work will shortly be commenced in connection with the construction of an electric railway from Hamburg to Ohlsdorf. Surveys have been completed.

Berlin Electric Traction.—The Charlottenburg Horse Tramway Company have obtained a concession for the use of electric traction from the Brandenburg Gate to the End Station.

Traction on Tramways.—Mr. Denny Lane, in a letter to a Cork paper, pins his faith to the use of gas motors on tramways. No one expected any other expression of opinion from him.

New Book on Telephony.—A work entitled "La Téléphonie," by M. Emile Pierard, has just been published by M. Ch. Desoer, Rue Gerardrie, Liège. It contains 224 illustrations, and is issued at the price of 8f.

That Weekly Paper.—The *Daily News* has just heard of the proposal to construct an electric railway to the top of Snowdon, and to which we referred in our issue of June 22. Better late than never, granny, eh!

Messrs. Lahmeyer and Co.—The balance-sheet for the past working year of the Elektricitäts-Aktiengesellschaft vorm. W. Lahmeyer and Co., of Frankfort-on-the-Maine, shows a deficit of about £2,000, but future prospects are good.

The Commercial Company's Cable.—Messrs. Siemens Bros. telegraph that the steamer "Faraday" completed the laying of the Commercial Cable Company's third Atlantic cable on Monday. The insulation is perfect. During the laying of the cable no hitch of any kind occurred, but operations were much impeded by dense fogs.

Internationale Druckluft und Elektricitats-Gesellschaft.—The gross receipts for the past year of this Berlin company amounted to £40,700, and mainly consisted of interest on advances made to the Paris company.

Electric Traction in St. Petersburg.—The secretary of the Imperial Institute of Engineers of Russia notifies that the tramway lines of St. Petersburg are to be equipped with the best street railway motors that can be obtained. Full particulars and specifications are obtainable from H. N. Mollwo, whose address is 72, English-quay, St. Petersburg.

The Next Cable Move.—The plague in Hong-Kong unfortunately continues, but the *Financial Times* having seen through the dodge, owing to our exposure, has ceased printing items about this epidemic from the *Cable Gazette*, whose next move, it may be expected, will be to spread news about the outbreak of swine fever on the west of Salisbury-court.

Electric Lighting at Essen.—The new building of the Rhenish-Westphalian Coal Syndicate has been lighted electrically. A 50-h.p. Deutz gas-engine supplies motive power to a 600-light dynamo. There are also accumulators for 400 lamps. At present there are installed 600 incandescent lamps and two arc lamps. The installation has been carried out by Herr Ringsdorff, of Essen.

Lighting of the Embankment.—The Works Committee of the London County Council have declined to carry out the electric light installation for Westminster and Waterloo Bridges and the embankment on the ground that the estimates of the Highways Committee were too low. The latter committee have proposed that the work should be put out to tender, and this will be considered next week.

The Brillie Meter.—The Brillié meter for the measurement of electrical energy, according to an article by M. Paul Robert in *Electricité* of June 21, has been considerably improved. Four years have elapsed since the introduction of this type of meter, which in its improved form possesses mechanical features different from those of the old class, and which have rendered the meter more of a practical character.

How Garnesdon Got Electricity.—The *Indian Engineer* of June 9 is kind enough to commence the publication, without the acknowledgment of the source, of the original piece of fiction that appeared under this heading in our issue of May 11. It is to be hoped that the fate of our Indian contemporary for this delinquency will not be the same as that of Mr. Rogers, the chairman of the Garnesdon Local Board.

Equal to Sheet Lightning.—An absurd proposal has just been submitted to the French Academy of Sciences by a too zealous electrician. He suggests, in order to prevent explosions in coal mines, that electricity should be employed for igniting fire-damp before the miners descend the shaft. This ridiculous proposal, which

Digitized by Google

if carried into practice would almost be a worse remedy than the evil itself, is about equal to the idiotic remarks made regularly by an electrical sheet.

French Electro-Metallurgical Company.—The following is the production of aluminium at the works of the French Electro-Metallurgical Company during the past four years :

	Neuhausen works.	Froges works.
1890	30 tons	7 tons.
1891	60 tons	20 tons.
1892	300 tons	60 tons.
1893	1,000 tons	260 tons.

Laundries.—A parliamentary paper has been issued giving the reports of her Majesty's inspectors of factories as to the condition of laundries, and among improvements suggested are the keeping down the temperature of the ironing-rooms by proper ventilation or fans where required. Where gas irons are used they should be such as do not emit offensive fumes. The steam should be conveyed from the wash-houses by ventilation or the use of fans. Here is a chance for the introduction of electrically-driven fans and of electric irons.

Electric Light at Dresden.—The central electric light station for lighting the Dresden railway stations comprises two Germania boilers, two Hartmann steam-engines, each of 330 h.p., and two rotary-current Siemens and Halske dynamos. By the end of the year the plant will be doubled, so that 1,320 h.p. will be available. It is intended to drive electric motors at the railway works. At present 100 arc and 400 incandescent lamps are connected. There will ultimately be about 600 or 700 arc lamps and 4,000 incandescent lamps.

Electric Boring Machines for Mines.—In a communication recently made to the Société de l'Industrie Minérale, M. Neu described the electric boring machines made by the Thomson-Houston Company. The author mentioned that the coal basin of the Nord and Pas-de-Calais could claim to be one of the first to introduce the application of electricity in mines, and also the use of electric locomotives, which were set in operation at Marles three years ago, and which were the first of this kind adopted in France for mining purposes.

Personal.—The council of the Society of Arts have awarded the society's silver medal to Mr. W. Worby Beaumont for his paper on "Automatic Balance of Reciprocating Machinery, and the Prevention of Vibration." The thanks of the council have been voted to Mr. W. H. Preece, C.B., F.R.S., for his paper on "Electric Signalling without Wires." Among the Civil List pensions granted by the Government during the year ended June 20 is one of £50 to Mr. Samuel Alfred Varley, in consideration of his services to electrical science.

The Magneto Hand Telephone.—Mr. Norman Hughes has written a booklet entitled "The Magneto Hand Telephone," which is published by Messrs. Spon and Chamberlain, of New York, and Messrs. E. and F. N. Spon, of 125, Strand, W.C. This little work is submitted to the consideration of all interested in telephony, with a view to enable other than licensees to benefit by the expiration of the main patent on the Bell telephone. It deals with the construction, fitting up, and adaptability to everyday use of the magneto hand telephone.

The French Thomson-Houston Company.—The Compagnie Française pour l'Exploitation des Procédés Thomson-Houston have declared a dividend on the past year's working of 5 per cent. The Company have decided to manufacture their electrical plant in France, and for this purpose the works of M. Postel-Vinay are to be acquired by a new company to be formed by the latter and by the Thomson-Houston Company. It has been resolved to increase the capital of the Thomson-Houston Company from £40,000 to £200,000.

A Water-Finder.—We learn from an Austrian electrical paper that Count Wrschowe Sekera von Sedczicz has met with much success as a finder of water, having discovered about 3,000 springs and only had about a dozen failures. He carries with him on his search platinum chains, a magnet, and a watch, and in consequence his system is amusingly referred to as an electrical method. The willow wand used by water wizards in this country has just as much to do with the finding of the water as anything electrical in connection with the count with the jaw-breaking name.

Electricity at Novare.—A central electricity station has been erected at Novare, on the right bank of the Quintino Sella Canal on the road to Milan. Water power to the extent of 300 h.p. is available, of which only 180 h.p. is at present utilised. There are two Jonval turbines driving a three-phase alternating-current dynamo of 19 amperes and 3,000 volts with a separate exciter. The central station is about a mile from the town, in the centre of which is a transformer station, where the pressure is reduced to 110 volts. The current is employed both for lighting and power purposes.

Legalising Electrical Units.—The United States House of Representatives have passed a Bill to define and establish the units of electrical measure. It gives legal recognition to the eight units of electrical measure adopted by the International Electrical Congress, which met in Chicago last autumn. These electrical units are the familiar units of resistance, current, and E.M.F., known as the ohm, the ampere, and the volt respectively. To these are added the unit of quantity, designated as the coulomb ; the unit of capacity, called the farad ; the unit of work, the joule ; the unit of power, the watt ; and the unit of induction, called the henry.

Union Elektricitats-Gesellschaft.— The annual report of this Company has been issued. During 1893 the Company constructed the electric tramways at Bremen and Remscheid, and commenced work on tramways in Hamburg, Erfurt, Gotha, and Brussels, which have since been put into operation. The length of these lines is about 41 miles. The Hamburg Street Tramway Company have also given an order for 42 miles of line and 105 motor cars. As the bulk of the work carried out during the past year was not paid for within the year the balance-sheet shows a loss of £8,457. In the current year this will be wiped off, and the directors expect that a satisfactory dividend will be paid.

The Brown Alternating-Current Motor.—Some interesting figures are given by M. Riccardo Arnò in the *Elettricista* of June 1 embodying the results of tests made with a Brown alternating-current motor of 11 kilowatts capacity at Intra in connection with the installation put down there for M. C. Sutermeister. This motor, which is designed for a frequency of 40 periods per second, a difference of potential of 150 volts, and an angular speed of 800 revolutions a minute, is 48cm. long, 60cm. wide, 61·5cm. high, and weighs 615 kilogrammes, including the pulley. It appears from the tests that the efficiency of the motor fully loaded was 88 per cent., and 50 per cent. at one-tenth of the load.

The Late M. Edmond Carre.—*L'Electricien* of June 30 announces the death of M. Edmond Carré, who was the first manufacturer of carbons for arc lamps, as invented by his brother, M. Ferdinand Carré. He was

Digitized by Google

born in 1823 at Moislains, Somme, and in 1868 established works in Paris for the manufacture of refrigerating machinery, but he did not come into prominence until the exhibition of 1878, when he showed various inventions of his brother, comprising refrigerating machinery, carbons, regulators, dielectric machines—receiving three gold medals and one silver medal. At the electrical exhibition of 1881 he obtained fresh successes with carbons and dielectric machines. The carbons brought him a handsome fortune.

Telegraphy with the Far East.—The twenty-fifth anniversary of the establishment of cable telegraphic communication with the Far East will be celebrated by a banquet at the Imperial Institute on Friday, the 20th inst., to be attended by gentlemen representing every section of the British Empire. The buildings and grounds will be specially arranged and illuminated for the occasion. Invitations to the reception state that guests are to have the honour of meeting the Prince of Wales, who, it is expected, will be accompanied by other members of the Royal family. An interesting feature of the celebration will be the display of cable telegraphic instruments in working communication with the four quarters of the world.

Lighting at Hastings.—The ceremony of switching on the electric light to the whole front esplanade, the three miles from the Fish Market to the end of the Marina, was performed on Saturday by the Mayor of Hastings (Alderman Tree). The light has been used for the illumination of a portion of the front for several years. In place of 15 lamps previously used, 52 2,000-c.p. lamps have been substituted, and these were turned on simultaneously in the presence of thousands of people. Previous to the ceremony there was a banquet at the Eversfield Hotel, presided over by Mr. H. M. Baker, chairman of the electric light company, and the guests included the mayors of Hastings and Winchester, and representatives of other municipalities.

The Electric Light in Warfare.—Some interesting experiments are to be carried out in connection with the use of search-lights for night attacks, and in the practice of besieging operations at Thorn by the German army during their forthcoming manœuvres. The plant consists of an 18-h.p. portable engine, with dynamo and search-light. The projector is not used directly, but through the medium of a mirror about 600ft. distant, so that the enemy is unable to fix the position of the plant. The mirror has an electric motor attached to it, which is connected to the dynamo by means of two cables. This allows of the mirror being moved to any desired angle by those in charge. A similar arrangement will be used in the naval manœuvres for the defence of ports.

Laying of New Mains.—The House-to-House Electric Light Supply Company intend to lay high-tension mains and to construct street boxes in Redcliffe-gardens and a short part of Fulham-road; the London Electric Supply Corporation are about to lay trunk mains in St. Thomas's-street, Maze Pond, Great Maze Pond, Snow's Fields, and Newcomen-street; the City of London Electric Lighting Company propose to lay mains across the Victoria-embankment at four points—namely, Temple-avenue, Carmelite-street, and each side of John Carpenter-street, and to connect the new mains with those in the subway of the embankment; and the Kensington and Knightsbridge Electric Lighting Company intend to lay mains and to construct street boxes in Stamford-road, Kensington.

Telegraphy in Africa.—The African Transcontinental Telegraph Company and the Portuguese Government have arrived at an agreement by which the latter undertakes to construct the telegraph line through the Portuguese sphere on the Zambesi, and will charge the company an annual rental for maintenance. There will be no telegraph station within the Portuguese sphere, and it is understood that the Government will make use of the Transcontinental Telegraph Company's material now on the spot in order to prevent delay in proceeding with the construction. A German daily paper prints an apparently inspired article contradicting the reports that the German Government had granted to an English company, or even to the English Government, a concession to construct a telegraph line in the German East African Protectorate.

Excursion to Antwerp.—As mentioned in our last issue, the Northern Society of Electrical Engineers have made arrangements for an excursion to the Antwerp Exhibition. A special saloon carriage will be attached to the train leaving the London-road Station, M.S. and L., Manchester, at 3 p.m. on Friday, July 20, arriving at Harwich at 9.20 p.m. The party will embark on the steamer which leaves Harwich (Parkeston Quay) at 10.15 p.m. and arrives in Antwerp at 10 a.m. Saturday. The party will return from Antwerp at 6.45 p.m. on Monday, July 23, arriving in Manchester at 3 p.m. the following day. Those members who do not find it convenient to travel from Manchester can join the party at Harwich. Mr. John Darney, the honorary secretary of the society, will be glad to hear from those who may be desirous of accompanying the party.

Electric Shot Firing.—Before the recent meeting of the North of England Institute of Mining and Mechanical Engineers, Mr. J. D. Kendall contributed a paper on misfires. In the course of the discussion, Mr. J. L. Hedley, H.M. inspector of mines, in regard to inferior detonators, suggested the desirability of using a galvanometer to test each detonator before it was sent into the mine; and as Mr. Kendall said defective fuse was the most abundant source of mis-fires, why not do away with the fuse altogether and use the electric battery. No doubt this suggestion would sound revolutionary to many miners, but if once adopted the change would never be regretted, and the evils and dangers arising from the present system of shot firing would to a great extent disappear. He was glad to learn that several gentlemen connected with mining in the district had taken the matter up in a way which would not only conduce to extra safety at their own mines, but would, he trusted, be the means of inducing others to take similar steps for the protection of their workmen.

Electric Lighting at Chemnitz.—About a year ago the Chemnitz Municipality instructed Messrs. Siemens and Halske to erect a central electric light station in that town. This is now completed and at work. Owing to the large area which had to be supplied, a system of high-tension rotary current has been employed, and the installation is the largest of this description in Germany. The station lies at the periphery of the town. There are three triple-expansion condensing engines, made by the Saxon Machinery Works, and these are of 220 effective horse-power. Each engine is coupled direct to a Siemens and Halske rotary-current dynamo, and also drives the continuous-current exciting dynamo. The capacity of each of the generating dynamos at 150 revolutions and full excitation is 180,000 watts, at a pressure of 2,000 to 2,200 volts. Concentric triple conductors carry the current to transformers in the neighbourhood where the current is to be used, the pressure being transformed to 120 volts. The low-pressure current is then further transmitted by concentric triple conductors.

"Vanity Fair" Unfair.—If the following quotation from *Vanity Fair* is a criterion of the accuracy—inaccuracy, we should say—of the personal paragraphs published in that paper under the title of the "Man of the Day," we

Digitized by Google

pity the recipients of these personals! Our contemporary, in writing of Mr. C. Grey Mott, says: "When 10 years ago an Act of Parliament was obtained for the construction of a subway between the Monument and The Elephant and Castle (which was to be worked by the endless cable system of America), he was persuaded to preside over the destinies of the company whose enterprise it was. Then, quickly recognising the difficulties that were ahead of the company, he began to study electricity as a means of locomotion, and studied it to such purpose that he presently and successfully worked out a system of electric traction which was in advance of the times; the result being that the company adopted his ideas." As a matter of fact the tunnel was carried out on the Greathead system; the three-rail electric system is that of Dr. Hopkinson; and the design of the first locomotives that of Messrs. Mather and Platt.

Plant for the Transmission of Power.—The recent terrible colliery disasters in South Wales and in Silesia point once more to the urgent necessity for a wider adoption of electricity for lighting and power purposes in mines, so as to minimise, if not practically prevent, the loss of life through explosions. In this connection the new catalogue issued by Messrs. John Davis and Son, of Derby, dealing with plant and apparatus for the transmission of power in mining and other operations, and for electrical illumination, comes out at an opportune moment. The Davis and Stokes's safety motor for use in fiery and dusty mines may be mentioned first. The safety commutator overcomes the difficulty of rendering sparking at the brushes harmless in an explosive atmosphere, and unless the commutator is securely closed, the motor fitted with it cannot be operated. The estimates given for electric lighting plant for mills, collieries, and private houses, for combined pumping and lighting plant, and for electric haulage plant, are interesting. A list of some of the various installations carried out on these lines is contained in the catalogue, where special protective fittings for incandescent lamps are priced and illustrated. The remaining portions of the list deals with steam dynamos, boilers, gas-engines, general fittings, switchboards, arc lamps, electric blasting apparatus, measuring instruments, telephones, etc.

The Proposed Pacific Cable.—The Inter-Colonial Conference, to which reference has been made in previous issues, was opened at Ottawa last week. The conference was engaged on Monday in the discussion of the Pacific cable question, which was brought forward by the Hon. F. B. Suttor (New South Wales). A paper was read by Mr. Sandford Fleming, in which he submitted proposals for the construction of the cable under an Imperial and colonial guarantee. The consideration of the subject was resumed on Tuesday and Wednesday. When the conference rose on Wednesday afternoon it was officially announced that a resolution had been passed endorsing the project of a Pacific cable free from foreign control, and asking the Imperial Government to cause an accurate survey to be made of the proposed routes at the joint expense of Great Britain, Canada, and Australasia. None of the colonies will commit themselves definitely to the scheme until the prospective cost has been ascertained. It is estimated that the cost of the preliminary survey would not exceed £25,000. A recent issue of the *Sydney Daily Telegraph* contains the following: "In view of a possibility that the Solomon Group will be included in the Pacific cable route, H.M. surveying ship 'Penguin,' which returned to port on May 5, will shortly commence some important work between Queensland and these islands. The ship is at present under orders to make a survey of Jervis Bay, and as soon as this work has been completed—probably in a month hence—she will proceed northward and take a line of soundings from a point north of Brisbane to the Solomon Islands in connection with the proposed Pacific cable. The ship will subsequently make a stay of several months in the islands, the officers meanwhile completing the survey of the group."

Gift to the Royal Institution.—The Royal Institution on Monday confirmed the acceptance by the managers of the offer by Mr. Ludwig Mond of a munificent endowment of scientific research. Last year Mr. Mond acquired the large freehold house, No. 20, Albemarle street, contiguous to the buildings of the Royal Institution. This house he has resolved to convey in fee simple to the Royal Institution, and to defray the expense of converting it from its present uses into a laboratory of chemical and physical research, to be called the Davy-Faraday Research Laboratory, and of equipping it with everything necessary for the conducting of scientific research upon a large scale. By this generous offer, Mr. Mond realises an idea which engaged the attention of Faraday and Brande and the managers of the Royal Institution half a century ago. The Davy-Faraday laboratory is to be placed under the management of a committee nominated by the managers of the Royal Institution from among themselves, while the laboratory will have a competent chief of its own, devoting all his time to its work. Mr. Mond desires that the resident professor at the Royal Institution should accept the position of director, thus further strengthening the ties between the Royal Institution and the laboratory as well as ensuring for the latter all the aid it is in the power of the Royal Institution to afford. The laboratory is to be free to all persons, without distinction of sex or nationality, who in the opinion of the managers of the Royal Institution are fully qualified to undertake scientific investigation, preference being naturally given to those who have actually done original work. After providing for all the needs of the Davy-Faraday research laboratory, the house given to the Royal Institution will afford space sufficient to provide a considerable addition to the accommodation of the Royal Institution itself.

High-Pressure Continuous-Current Transmission.—A concession was granted some time ago for the erection and working for 40 years of an electric light station in the town of Sigmaringen. This installation, which has been carried out by the Schuckert Company, comprises two main features: (1) the electrical transmission of power by means of high-tension direct current, and (2) electric light plant in conjunction with accumulators. With regard to the latter, the installation is arranged on the three-wire system, the conductors being partly carried overhead and partly underground. The batteries are of the Pollak type. At Lauchterthal, just over three miles distant from Sigmaringen, is a fall of water which has been profitably used in this undertaking. The turbines in which the water, which has a fall of 30ft., is utilised are two in number, having been furnished by Mr. J. M. Voith, of Heidenheim. They are each of 182 h.p. One drives a dynamo and the other supplies power for the working of the Lauchterthal rolling-mill. The generating station contains three four-pole dynamos, one of which is kept as reserve, and each of which at 460 revolutions a minute gives a continuous current of 61 amperes at 1,100 volts. The transmission is effected on the three-wire system, two of the dynamos being connected in series, and thus yielding 2,200 volts. At the secondary station in Sigmaringen are installed three similar four-pole motors coupled direct to dynamos of the same type. The motors each give off about 70 h.p., which is directly trans-

Digitized by Google

mitted to the dynamos, which at a mean pressure of 260 volts yield 170 amperes; the two motors at work are, of course, united in series, the third forming a stand-by. A portion of the current is utilised for charging accumulators and partly for direct supply. The number of lamps connected is 3,000 incandescents and 20 arc lamps, whilst several electric motors are also energised.

The Transmission of Rectified Currents.—In the *Electrical Engineer* of May 4 was given an illustrated description of the Hutin and Leblanc system and apparatus for the conversion of alternating into direct currents. An interesting application of this method in the transmission of electrical energy between La Chapelle and the Epinay railway station has now been carried out for the Northern of France Railway Company. The problem which MM. Hutin and Leblanc had to solve was as follows: given a continuous current at from 110 to 170 volts, furnished by an Edison dynamo at La Chapelle electricity works, and working only a few hours a day, to transmit the current to the Epinay railway station and to utilise it in the charging of accumulators for the lighting of the station. The distance separating the electricity works and the railway station is about five miles. The solution of the problem was found in the use of rectifiers. For this purpose a frequency and pressure transformer has been put down, this converting the direct current at the electricity works into an alternating triphase current of from 4,500 to 6,000 volts. A similar apparatus at the receiving end of the line—that is, at the railway station—is employed for retransforming this triphase alternating current into direct current. The electricity works contain an Edison dynamo capable of giving 100 amperes at from 110 to 200 volts. The transformer located here is of 15 kilowatts capacity. An identical transformer, as already mentioned, is arranged at the railway station, and supplies the current to a battery of accumulators, the object of which is to energise 64 incandescent lamps, which constitute the illumination of the station. Our French contemporary *Electricité*, from which this information is abstracted, states that as a result of the Epinay experiments it may be concluded that the efficiency of a fairly important transmission scheme on the Hutin and Leblanc system may reach 90 per cent., including the loss in the line.

Phosphorescence.—The production of liquid oxygen in considerable quantities at the Royal Institution has afforded a convenient means of investigating the behaviour of substances exposed to light at a temperature of 180deg. below zero, and at a meeting of the Chemical Society held on Thursday last week at the Royal Institution, Prof. Dewar gave an account of the researches which he has lately been carrying out in this direction. Finding that at low temperatures chemical action is almost, if not quite, in abeyance, Prof. Dewar was led to try whether photographic action also ceases. He found that it does not, though it is diminished by 80 per cent. or more. While investigating this, he noticed that the apparatus with which he was working was phosphorescing brightly, and he was thus induced to study phosphorescence itself at low temperatures. Beginning with gelatine and celluloid—substances which he was using in his photographic experiments—he found them to be very luminous when cooled to 180deg. and exposed for a second to the beam of a strong electric light. In the same way phosphorescence was produced in numerous other organic substances, such as ivory, bone, indiarubber, egg-shell, feathers, cotton-wool, linen, leather, blossoms of flowers, etc. Naturally the question presented itself of the relation of phosphorescence to structure. Prof. Dewar therefore experimented with various definite organic compounds. From these and other experiments he is led to the provisional generalisation that the more complex a body is in structure, the more likely it is to phosphoresce, perhaps because in some way its structure enables it to take up the light-vibrations with the more facility. The capability of oxygen for phosphorescing is another curious fact. In the gaseous state it can be made to glow if exposed to an electric spark while rushing into a large vacuum tube. This property is shared by its compounds, but is not possessed by hydrogen or any other gas. Here, strange to say, the presence of a trace of organic matter destroys the effect. Prof. Dewar stated that a drop or two of ether or of scent in the room would make the experiment impossible for hours. That the phosphorescence is due to some kind of molecular change in the oxygen is indicated by the fact that ozone, among other products, is formed during the process.

An Electric Steering Compass.—A new electric steering compass has been devised by Lieutenant Bersier, of the French navy. In this appliance the needle of the compass actuates the rudder by means of an electric current, and thus precludes the possibility of any error on the part of a living steersman from fatigue or confusion. The difficulty of constructing such a compass hitherto has been owing partly to the heaving of the ship, and partly to the difficulty of causing the delicate needle or card to act on the steering gear without impeding its motion. In Lord Kelvin's compass, for example, the card is merely a skeleton disc of paper, silk thread, and aluminium with eight parallel wires of magnetised steel underneath, and it rests freely on a point or pivot of iridium or other hard metal by means of a cup of ruby or sapphire. The slightest contact with another body would disturb its motions in the magnetic field of the earth. M. Bersier, according to the *Times*, gets rid of all contact by making the current form a Ruhmkorff coil spark from a metal point on the edge of the card to semi-circular plates of metal insulated from each other and from the sides of the compass bowl in which they are fixed. The coil is excited by a battery if there is no electric lighting installation on the vessel; and a current of two to three amperes is sufficient. A wire from the coil leads to the pivot of the card and the cup over it, from which a light wire along the radius of the card corresponding to "north," conveys the current; and according as the ship is to right or left of the course a spark three centimetres long passes to the right or left plate in the bowl and excites one or other of two electromagnets forming the circuit of a small electromotor. This motor works the steering motor like the hands of a man. The mechanism can be applied to any existing steering gear. The new compass has been tried in the French squadron for several months past, and is said to have succeeded perfectly well. The compass card seems quite indifferent to the spark, probably because the current of the coil is alternating and of low strength. Moreover, certain precautions are taken in producing the spark, and the coil and electromagnets are at some distance, about five metres from the compass. The new compass also registers all variations, of course, if desired, the spark piercing a band of paper which is moved by clockwork up the bowl. Moreover, by a simple arrangement of Geissler tubes, steering orders can be automatically transmitted, and the course changed from any part of the ship. In practice the compass enables a course to be steered to a fraction of a degree—that is to say, with much greater precision than by hand, and it is claimed that it is specially suitable for passenger steamers such as the Atlantic liners, as it would enable them to travel in a straighter line, thus saving both time and money. It also permits the vessel to be steered from the masthead compass.

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 719, Vol. XIII.)

§ 25. *Moment of a couple* is the product of either force into the arm. Its dimensional expression is therefore

$$[G]=[F\,.\,L]=[M\,L^2\,T^{-2}].$$

Moment of inertia of a set of bodies round any axis is the sum of the products of each mass into the square of its distance from the axis. If the masses be $m_1\ m_2\ m_3\ \ldots$ and the distances be $r_1\ r_2\ r_3\ \ldots$ then $I = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2\ \ldots$

$$= \Sigma m r^2 = k^2 \Sigma m = M k^2$$

where k is called the radius of gyration, and may be defined as the radius of an infinitely thin rim in which all the masses may be supposed to be concentrated, so as to leave the moment of inertia of the system unaltered. Its dimensional formula is therefore $[I]=[M\,L^2]$.

Moment of momentum of a moving body round any point is the product of its momentum into the perpendicular distance from the point on its line of motion. Its dimensional formula is therefore $=[M\,.\,v\,.\,L]=[M\,L^2\,T^{-1}]$. If we make use of the analogues, that moment of a couple in rotational motion is analogous to force in translational motion, and moment of inertia to mass, we get the following convenient and useful relations:

Translational motion.	Rotational motion.
$a=\frac{F}{M}$	$\dot{\omega}=\frac{\text{moment of couple}}{\text{moment of inertia}}=\frac{G}{I}$
$v=a\,t=\frac{F}{M}\,.\,t$	$\omega=\dot{\omega}\,t=\frac{G}{I}\,.\,t$
$M\,v=F\,t$	$I\,\omega=G\,t$
$s=\frac{1}{2}\,a\,t^2$	$\theta=\frac{1}{2}\dot{\omega}\,t^2$
$=\frac{1}{2}\cdot\frac{F}{M}\cdot\frac{M^2\,v^2}{F^2}$	$=\frac{1}{2}\,\frac{G}{I}\cdot\frac{I^2\,\omega^2}{G^2}$
$F\,s=\frac{1}{2}\,M\,v^2$	$G\,\theta=\frac{1}{2}\,I\,\omega^2$

If the linear velocity be V, and the angular velocity be Ω, at the zero of reckoning, then the resulting equations would be $M\,(v-V)=\pm F\,t$; $\frac{1}{2}\,M\,(v^2-V^2)=\pm F\,s$; $I\,(\omega-\Omega)=\pm G\,t$; $\frac{1}{2}\,I\,(\omega^2-\Omega^2)=\pm G\,\theta$. (See § 24.)

§ 26. *Activity* is a word introduced by Lord Kelvin to signify "time-rate of doing work." Its dimensional formula is therefore $[A]=[W\,T^{-1}]=[M\,L^2\,T^{-3}]$. The unit rate of working used by engineers in this country is *one horse-power*—that is, 550 foot-pounds per second. In the metric system this is equivalent to 76 metre kilogrammes per second. Unit rate of working, or unit activity, on this system is one *erg* per second. In practical electricity a *watt* is generally employed as the unit of activity, and is equivalent to 10^7 ergs per second. One *watt* is a joule per second. 1 h.p. = 746 watts.

Density of a body is the quantity of matter in unit volume of it. Specific gravity of a body is the ratio of the weight of any volume of it to the weight of an equal volume of water. In the metric system unit volume of water is unit mass, but this is not so on the British system. Hence in the metric system the same number expresses the density and the specific gravity of the body, whereas on the British system the density of a body is equal to its specific gravity multiplied by 62·5, since one cubic foot of water weighs approximately 62·5lb. Specific gravity being a ratio, its value must be the same whatever system of units we use, and its dimensional formula must necessarily be unity. The dimensional formula for density is

$$[s]=[M/V]=[M\,L^{-3}]$$

§ 27. In the theory of elastic bodies any modulus is stress divided by strain, and the different moduluses are obtained by defining the stress and the strain in particular ways. A strain is any change in the shape or in the bulk of a body, and stress is the name given to the forces which produce this strain. Thus bodies can have two distinct kinds of elasticity—namely, elasticity of shape, or rigidity modulus, and elasticity of bulk, or bulk modulus. Fluids have a bulk modulus in perfection, but have no rigidity modulus. Solids have both a bulk modulus and a rigidity modulus, but neither of them in perfection. *Strain* is a mere ratio of length to length, or volume to volume, and hence its dimension is unity. *Stress* is invariably given in units of force per unit of area, and its dimensional formula is therefore

$$[M\,L^{-1}\,T^{-2}].$$

Rigidity modulus, n, is the tangential forces (shearing forces) per unit area, divided by the shear produced. Here shear is defined as an angle. If a cube be taken, then the deformation from a right angle expressed as a fraction of a radian is the shear.

Bulk modulus, k, is the hydrostatic forces per unit area divided by the change in volume per unit volume.

Young's modulus, M, is the stretching forces per unit area divided by the elongation produced per unit length.

$$M = \frac{1}{\frac{1}{3n}+\frac{1}{9k}} = \frac{9nk}{3k+n}.$$

(See Thomson and Tait, "Natural Philosophy," § 683, p. 221.)

Hence the dimensional formula for rigidity modulus, n, bulk modulus, k, and Young's modulus, M, is, in each case, $[M\,L^{-1}\,T^{-2}]$.

§ 28. Torsional rigidity and flexural rigidity depend not only on the material but on the shape and on the axis round which torsion or flexure is taken. Torsional rigidity of a bar may be defined as the couple that produces unit twist in it per unit length, and its flexural rigidity in any given plane as the couple that would produce in it unit curvature in this plane. Let N denote torsional rigidity and N^1 flexural rigidity, then

$$[N] \text{ or } [N^1]=[M\,L^3\,T^{-2}].$$

For a symmetrical rod the torsional rigidity is equal to the rigidity modulus of the material of which it is made multiplied by the moment of inertia of the cross-section round the proper diameter. Hence its torsional rigidity is proportional to the product of the rigidity modulus and the square of its cross-section, and therefore the dimensional formula is

$$[N]=[M\,L^{-1}\,T^{-2}]\times[L^4]=[M\,L^3\,T^{-2}].$$

The flexural rigidity is proportional to the product of the Young's modulus and the square of the cross-section. Hence its dimensional formula is

$$[N^1]=[M\,L^{-1}\,T^{-2}]\times[L^4]=[M\,L^3\,T^{-2}],$$

the same as otherwise found above.

§ 29. *Surface tension* of liquids is given in units of force per unit of length. Its dimensional formula is therefore

$$[\tau]=[M\,L\,T^{-2}]\div[L]=[M\,T^{-2}].$$

This is equivalent to energy per unit area.

§ 30. *Viscosity* is a property possessed not only by liquids and gases, but by the most elastic of solids. To define the viscosity of a fluid, suppose you have a layer of unit thickness of it between two planes of indefinite extent to each of which the fluid adheres. Let one plane be fixed: then the tangential force per unit area necessary to move the other plane with unit velocity is the measure of the viscosity of the fluid.* It is, therefore, tangential force per unit area divided by shear per unit time.

The dimensions of viscosity will therefore differ from the dimensions of stress simply by the time unit, just as the dimensions of velocity differ from those of acceleration. Hence the dimensional formula for viscosity is

$$[\mu]=[M\,L^{-1}\,T^{-1}].$$

The viscosity of water diminishes with rise of temperature,

* "The *viscosity* of a liquid (or the numerical reckoning or measure of the viscous quality) is defined as the tangential force per unit area, in either of the mutually perpendicular planes of zero elongation, of a simple distortion, required to produce change of shape at unit speed."—Kelvin, "Mathematical and Physical Papers," vol. viii., p. 437.

Digitized by Google

and Poiseuille, who investigated the flow of water through capillary tubes, gives

$$Q = 1836{\cdot}724\ (1 + 0{\cdot}0336793\,t + 0{\cdot}0002209936t^2)\ \frac{H\,D^4}{L}\ *,$$

where Q is the quantity of water in cubic millimetres that, at temperature t, flows in one second through a capillary tube of length L, and diameter D, under a pressure of a mercury column of height H. Reducing to C.G.S. units, and neglecting figures after the fifth decimal place, this gives

$$Q = 1350\ (1 + 0{\cdot}03368\,t + 0{\cdot}00022\,t^2)\ \frac{p\,D^4}{L}.$$

where Q = quantity in cubic centimetres that flows through in one second;
p = the pressure at the mouth of the capillary tube in grammes weight per square centimetre (approximately equal to the head of the water);
D = diameter of the capillary tube in centimetres;
and L = length " " " "

But it can be shown that for laminar motion

$$Q = \frac{\pi}{128\,\mu} \times \frac{p\,D^4}{L},$$

where μ is the viscosity of the water.

$$\therefore \mu = \frac{1{\cdot}818 \times 10^{-5}}{1 + 0{\cdot}03368\,t + 0{\cdot}00022\,t^2} \text{ gms. wt. per sq. cm.}$$

Thus $\mu_0 = 1{\cdot}818 \times 10^{-5}$ grammes weight per sq. cm.
$\mu_{100} = {\cdot}277 \times 10^{-5}$ " " "

The viscosity of water at 100deg. C. is less than a sixth of the viscosity of water at 0deg. C.

§ 31. "The diffusivity of one substance in another is the number of units of the substance which pass in unit of time through unit of surface, across which the gradient of concentration is unit of substance per unit of volume per unit of length."†

"*Diffusivity* is essentially to be reckoned in units of area per unit of time,"‡ and its dimensional formula is therefore $[\kappa] = [L^2\,T^{-1}]$.

In art. xcviii., of Kelvin, "Mathematical and Physical Papers," vol. iii., p. 428, it is shown that the same law governs the following five cases of diffusion:

I. Motion of a viscous fluid.
II. Closed electric currents within a homogeneous conductor.
III. Heat.
IV. Substances in solution.
V. Electric potential in the conductor of a submarine cable when electromagnetic inertia can be neglected.

See also, in this connection, Tables A, B, and C, pages 207 and 208 of the same volume.

It may be remarked that the diffusivity of fluid for viscous motion is its viscosity divided by its density, and therefore $[\kappa] = [M\,L^{-1}\,T^{-1}] \div [M\,L^{-3}] = [L^2\,T^{-1}]$.

INTERRUPTIONS AND REPAIRS OF CABLES AND LAND LINES.

The following table, which has been forwarded to us for publication, is self-explanatory, but scarcely agrees with Sir J. Pender's views given in another column.

	Date of interruption.	Date of repair.
Brest—St. Pierre cable, P. Q. Co..	March 28, 1894	June 13, 1894.
Accra—Kotonou cable	April 1, 1894..	June 14, 1894.
Accra—Lagos cable	May 21, 1894..	June 6, 1894.
Bagdad—Fao land line	June 5, 1894...	June 6, 1894.
Bagdad—Fao land line	June 11, 1894.	June 12, 1894.
Saigon—Bangkok land line.....	June 27, 1894.	June 28, 1894.
Brest—St. Pierre cable, Anglo ...	April 6, 1893..	Still interrupted.
Bissao—Bolama cable	Nov. 24, 1893.	
Assab—Massowah cable	May 30, 1894..	
Tarifa—Tangiers cable	June 9, 1894...	
Sierra-Leone—Accra cable.....	July 2, 1894 ...

PRACTICAL NOTES ON DYNAMO CALCULATION.—IV.*

BY ALFRED E. WIENER.†

10. *Armature Insulations.*—According to the size and the voltage of a dynamo the thicknesses of the insulations in its armature vary in very wide limits.

The coating of the armature conductor, if single wire is employed, usually is effected by a double cotton covering, ranging in diametrical thickness from ·012in. to ·020in., according to the size of the wire and the voltage. If stranded cable is used for winding the armature, either bare or single cotton-covered wire is used to make up the cable, and the whole is covered with two or three layers of cotton. The thickness of the single cotton insulation in this case varies from ·005in. to ·010in. in diameter. For very thin wires, from No. 20 B.W.G. (·035in.) down, a double silk covering from ·004in. to 005in. diametrical thickness is applied.

In case of rectangular or wedge-shaped conductors, according to their size and to the voltage of the machine, either a double cotton covering, as with wires, is used, or oiled paper, cardboard, asbestos, or mica is employed for their enwrapping or separation. The thickness of the insulation in the latter case varies between ·010in. and ·020in. each side.

Besides this coating of the single conductors, sometimes—particularly in high-voltage machines—a sheet of insulating material is employed to separate the layers from one another. The thickness of this insulation, for which either oiled paper, rubber tape, or silk is used, ranges from ·007in. to ·030in.

The insulation of the conductors from the iron body in smooth armatures is effected by serving the core with one or two coatings of enamel or japan, and then covering it by either oiled paper, cardboard, canvas, silk, tape, sheet rubber, cotton cloth, asbestos, or mica, varying in radial thickness between ·012in. and $\frac{3}{16}$in.

For toothed and perforated armatures this core insulation is carried out in form of paper, or cardboard, or vulcanised fibre tubes or channels, fitted into the grooves, or—especially in large toothed core machines—by means of mica troughs lining the bottom and the sides of the slots. The thickness of this lining ranges from ·010in. to ·125in., proportional to the size of the slots, and according to the voltage of the dynamo.

11. *Arrangement of Armature Winding.*—By "arrangement" of the armature winding is understood the grouping of the conductors into a number of armature coils, each containing a certain number of turns, or convolutions, of the armature wire, and each one corresponding to a division of the collector or commutator.

The E.M.F. generated by the combination of a series of convolutions, or by a coil, while under the commutator brushes is not constant, but fluctuates with the rate of its cutting lines of force in the different positions during that period. This fluctuation of the E.M.F. of a dynamo consequently increases with the angle which is embraced by each coil of the armature, and can be mathematically determined from the measure of this angle. In a 10-coil armature, for instance, the angle embraced by each coil is 36deg., and the fluctuations of the E.M.F. are calculated to amount to ± 2·4 per cent. of the total E.M.F. generated. With a 12-division commutator, the angle enclosed by each armature coil is 30deg., and the fluctuations figure to ±1·7 per cent. For an 18-bar commutator, the coil angle is 20deg., and the fluctuations are found to be reduced to ± 1 per cent. For 24 divisions in the commutator, the angle is 15deg., to which correspond fluctuations in the amount of about ± ½ of 1 per cent. With 36 bars the angle is 10deg., and the fluctuations ± ⅓ of 1 per cent.

* From the *Electrical World* (New York).
† The following typographical errors occurred in the section of this article published in these columns June 22: Page 722, first column, thirty-eighth line from top, "In the average values . . . " should read, "In Table III. the average values . . . " In Fig. 1, page 722, the expression for the pitch of the slots should be $\frac{da' \times \pi}{n'}$, instead of $\frac{da \times h}{n'}$; for the width of the slot, in Figs. 1 and 3, pages 722 and 723, the letter s should be used instead of S; in Fig. 2, page 723, the diameter of the whole should be designated by $\delta a'$ instead of δa.

Digitized by Google

For 48 divisions the angle is 7½deg, and the fluctuations $\pm \frac{1}{10}$ of 1 per cent. For 90 divisions the angle is 4deg., and the fluctuations $\mp \frac{3}{1000}$ of 1 per cent. With a 360-division commutator, finally, the angle enclosed by each coil is 1deg., and the fluctuations of the E.M.F. reduced to but $\frac{3}{1000}$ of 1 per cent.

From these figures it is apparent that the fluctuations become practically insignificant, or the potential of the machine practically steady, if, for bipolar dynamos, armature coils of an angular breadth of less than 10deg., or, what amounts to the same thing, if commutators with from 36 divisions upward, are used. For low-potential machines, up to 300 volts, it has been found good practice to provide, per pair of poles, between 40 and 60 divisions in the commutator.

For high-potential dynamos the voltage itself determines the number of commutator bars. For in these the self-induction set up in the separate coils and the sparking at the commutator caused by the potential of this self-induction between two adjacent commutator divisions, are more important considerations than the fluctuation of the E.M.M.

No potential below 20 volts is able to maintain an arc across even the slightest distance between two copper points. The potentials above this figure necessary to carry an arc over a certain distance depend upon the intensity of the current. In order to maintain, between two copper conductors, an arc of ·040in. length—the usual thickness of the commutator insulation for high-voltage machines—according to actual experiments made by the author, imitating as nearly as possible the conditions of a commutator, a current of

100	amperes	takes 20	volts
50	,,	,, 21	,,
20	,,	,, 23	,,
10	,,	,, 25	,,
5	,,	,, 30	,,
2	,,	,, 40	,,
1	,,	,, 50	,,

From this it can be concluded that, in order to prevent the commutator of a high-voltage machine from becoming unnecessarily expensive, allowances have to be made as follows:

TABLE XVI.—Differences of Potential Between Commutator Divisions.

Current intensity per pole.	Difference of potential between commutator divisions.
Over 100 amperes	10 to 20 volts
100 to 50 ,,	12 ,, 21 ,,
15 ,, 20 ,,	15 ,, 23 ,,
20 ,, 10 ,,	20 ,, 25 ,,
10 ,, 5 ,,	25 ,, 30 ,,
5 ,, 2 ,,	30 ,, 40 ,,
2 ,, 1 ,,	35 ,, 50 ,,

The respective minimum numbers of commutator divisions, consequently, are:

$$\left.\begin{array}{lll}
\text{For over 100 A. p. pole } n_{min} & = \frac{E \times 2P}{20} & = \frac{E \times P}{10} \\
\text{For 100 to 50 A. p. pole } \ldots & = \frac{E \times 2P}{21} & = \frac{E \times P}{10{\cdot}5} \\
\text{For 50 to 20 A. p. pole } \ldots & = \frac{E \times 2P}{23} & = \frac{E \times P}{11{\cdot}5} \\
\text{For 20 to 10 A. p. pole } \ldots & = \frac{E \times 2P}{25} & = \frac{E \times P}{12{\cdot}5} \\
\text{For 10 to 5 A. p. pole } \ldots & = \frac{E \times 2P}{30} & = \frac{E \times P}{15} \\
\text{For 5 to 2 A. p. pole } \ldots & = \frac{E \times 2P}{40} & = \frac{E \times P}{20} \\
\text{For 2 to 1 A. p. pole } \ldots & = \frac{E \times 2P}{50} & = \frac{E \times P}{25}
\end{array}\right\} \quad (15)$$

Having thus determined the minimum number of divisions that can be used in the commutator without excessive sparking, the actual number, n, to be employed has to be chosen by comparing this value of n_{min} with the total number of conductors on the armature, found by multiplying the rounded result of equation (8), (9), or (10) respectively, with that of formula (11), and dividing the product by the number, p, of armature wires stranded in parallel.

The number of turns, m, of armature conductors per commutator division, or the number of convolutions in each armature coil, is then readily obtained by dividing the total number of armature convolutions by the number of coils, n. The number of armature convolutions in ring armatures is identical with the number of armature conductors, while in drum armatures it takes two conductors to make one turn, and, therefore, the number of turns is but one-half the number of conductors. Hence we have:

For ring armatures:

$$m = \frac{o \times u}{n \times p} \quad \ldots\ldots \quad (16)$$

and for drum armatures, or drum-wound ring armatures:

$$m = \frac{o \times u}{2 \times n \times p} \quad \ldots\ldots \quad (17)$$

If the armature is to have spacing strips, or driving horns, the number of the armature divisions for this purpose depends upon the number of armature coils, n, the number of turns per coil, m, and the number of conductors in parallel, p.

In ordinary machines the number of armature divisions is usually made equal to the number of coils, n, and sometimes—especially in drum armatures—double the number of coils, $2n$, is taken. For high-current output machines often a greater number of armature divisions than that given by the number of coils is chosen. In such a case the total number of single wires, or cables, $m \times n \times p$, is to be suitably arranged in groups. The number of these groups is to be a multiple of the number of coils, n, and since the number of turns per coil, m, in high-current dynamos, is usually $= 1$, the problem of grouping, in this case, amounts to subdividing the number of parallel wires, p.

12. *Radial Depth of Armature Core—Density of Magnetic Lines in Armature Body.*—Diameter and length of the armature core being determined, its proper radial depth can be readily found by the cross-section to be provided for the passage of the magnetic lines of force.

The density of lines permitted per unit area of armature cross-section is limited by the heating of the armature due to hysteresis and eddy-current losses. The heat generated by either of these causes increases with the density of the lines, and with the number of magnetic reversals per second. The latter number is the product of the number of revolutions per second and the number of magnet poles, and therefore it is obvious that in order to keep the temperature increase of the armature in its practical limits, in dynamos where this product is great, larger specific sectional areas of the armature core are to be allowed than in machines having a small number of magnetic reversals, or a low "frequency," as half the number of reversals, or the number of complete magnetic "cycles," is called. The former—high frequency—is the case for high speed and multipolar dynamos, the latter—low frequency—for slow-speed and bipolar ones. On the other hand, large multipolar machines generally have well-ventilated ring armatures, and in these an even considerably larger amount of heat generated will produce a smaller temperature increase than in drum armatures of equal output.

According to these considerations, the following values of the densities of lines of force in the armature core are recommended:

TABLE XVII.—Core Densities for Various Kinds of Armatures.

Kind of armature.	Density of lines of force. Per square inch.	(Gausses.)
Slow-speed bipolar drum.....	50,000 to 80,000	8,000 to 12,500
,, ,, ring	80,000 ,, 120,000	12,500 ,, 18,500
High-speed ,, drum.....	40,000 ,, 70,000	6,000 ,, 11,000
,, ,, ring	60,000 ,, 90,000	9,000 ,, 14,000
Slow-speed multipolar drum..	30,000 ,, 60,000	4,500 ,, 9,000
,, ,, ring ...	50,000 ,, 80,000	8,000 ,, 12,500
High-speed ,, drum..	25,000 ,, 50,000	4,000 ,, 8,000
,, ,, ring...	40,000 ,, 70,000	6,000 ,, 11,000

The cross-section of the magnetic circuit in the armature core is the product of the net length, and the net the radial depth of the core, and of the number of poles; and this product, divided into the total magnetic flux through the armatures, gives the density of lines per unit area. In

Digitized by Google

order to obtain the net radial depth or breadth of the cross-section of any armature core, therefore, the total armature flux is to be divided by the product of the armature density, of the net length of the body, and of the number of poles:

$$b_a = \frac{\phi}{2\,P \times \mathfrak{B}_a \times l_a \times k_1} \quad . \quad . \quad . \quad (18)$$

The symbols used in this formula denote:

b_a = radial depth, or breadth of cross-section of armature core, in inches;

ϕ = useful flux, in webers, or number of useful lines of force cutting armature conductors, the calculation of which will be the subject of a subsequent chapter (Part II., Chapter 1); for determining the radial depth of toothed and of perforated armatures, this is to be multiplied by the factor of core leakage (see Table XI., Chapter 8);

$\mathfrak{B}_a$ = density of magnetic lines in armature body, in lines of force per square inch, given in Table XVII.;

P = number of pairs of magnet poles;

l_a = length of armature core in inches, from formula (12);

k_1 = ratio of net iron section to total cross-section of armature core (see Table XVIII.).

The constant k_1 depends upon the material and the manner of building up of the armature core. In order to prevent excessive losses and resulting heating of the armature due to eddy currents in the iron, it is necessary to laminate the body perpendicular to the direction of the active armature conductors. In case the active pole faces embrace either the outer, or the inner, or both circumferences of the armature, the active conductors are those parallel to the shaft, and the lamination of the core is to be effected perpendicularly to the shaft; while in case of the poles being at the sides of the armature (flat-ring type), the active conductors run perpendicular to the shaft, and the lamination is to take place parallel to the shaft. In case of the pole-pieces embracing three sides of the armature section, finally, the active conductors are partly parallel and partly perpendicular to the shaft, and the lamination in consequence is also to be carried out in both directions. The materials for effecting these various laminations are iron discs, iron ribbon, and iron wire respectively. The insulation of these laminæ in the majority of machines has been, and is yet, effected by inserting sheets of thin paper, asbestos, etc., between them, although it has been repeatedly shown by practical experiments* that such an insulation is not only entirely unnecessary, but, on the contrary, even disadvantageous, For, in order not to lose too much of the available sectional area of the body, the lamination in such armatures is usually made rather coarse, but it is just the fineness of the lamination, and not the thickness of its insulation, that avoids in a higher degree the generation of eddy currents. The oxide coating created by heating the iron is a very effective and suitable insulation of the armature core laminæ.

In the following table, values of the ratio, k_1, of the net to the total core section are given for various thicknesses of the iron, and for the different modes of insulation now in use:

TABLE XVIII.—Ratio of Net Iron Section to Total Cross-section of Armature Core.

Material.	Thickness, in inches.	Insulation.	Value of k_1.
Sheet iron (discs or ribbon)...	·080	Paper or asbestos	·95 to ·90
,, ...	·040	,, ,,	·92 ,, ·88
,, ...	·020	Paper or enamel	·90 ,, ·85
,, ...	·010	,, ,,	·85 ,, ·80
,, ...	·010	Oxide coating	·95 ,, ·90
Square wire.....	·080	Cotton covering	·90 ,, ·80
,, ,, ...	·040	,, ,,	·85 ,, ·75
,, ,, ...	·020	Enamel or varnish	·80 ,, ·70
,, ,, ...	·020	Oxide coating	·90 ,, ·85
Round wire	·080	Cotton covering	·80 ,, ·70
,, ,, ...	·040	,, ,,	·75 ,, ·65
,, ,, ...	·020	Enamel or varnish	·70 ,, ·60
,, ,, ...	·020	Oxide coating	·85 ,, ·80

In large ring armatures, for the sake of ventilation, air-spaces are provided in modern machines by means of light brass frames inserted in certain intervals between the core discs. In calculating the radial depth, b_a, of the body the sum of these distance-pieces is to be deducted from the total length, l_a, of the core, the reduced length so found being used instead of l_a in formula (18).

(To be continued.)

GAS v. STEAM FOR CENTRAL STATIONS.

In his paper read towards the end of 1892 before the Manchester Association of Engineers, Mr. B. H. Thwaite directed attention to the possibilities of the use of gas for various purposes when generated in the coalfields as a heat-giver rather than as a light-giver. This paper of Mr. Thwaite's will be found in our issues of December, 1892, and it gave rise to much thoughtful consideration amongst electrical engineers, so much so that more than one prominent engineer examined carefully into the subject. We do not, however, find that many English engineers have been bold enough to specify gas-engines for central-station work. We have, however, before us a report to one of our large towns which deals with the question, and it may interest our readers to know somewhat of the matter. In the first place, the authority was particularly desirous of obtaining an investigation into the comparative merits of steam and gas, and with this view instructed their consulting engineer to report, firstly, upon an installation of a temporary character for 1,000 16-c.p. lamps, to be afterwards extended into a complete installation for 10,000 16-c.p. lamps burning simultaneously. The question was between Dowson gas and steam, it being accepted that unless ordinary gas could be supplied at 1s. per thousand its use was out of the question. This price for ordinary gas not being likely, its use was not considered. The comparison was made between a typical set of steam plant and a typical set of gas plant. The steam plant would consist of a Lancashire double-flued steel boiler, a Willans central-valve compound non-condensing engine, and a suitable dynamo driven direct from the engine as a unit. The gas plant, of a Dowson generating set, a Crossley gas-engine, and a suitable dynamo driven by means of a belt. One of the most important considerations in such a comparison is the ground area required by the different systems, and in this respect steam is easily first. The importance of this where land is dear and not easily obtainable is clear. In the particular case before us the available land is insufficient for the extensions, and the requisite area would have to be made up by taking from a baths site—a serious inconvenience. But by far the most important consideration is that of the noise from the exhausts of these gas-engines—a matter which is troublesome everywhere, but especially so in crowded localities. In the complete scheme, as contemplated in this instance, there would be no less than 17 different and distinct exhausts, all from the largest type of engine, 35 h.p. nominal, each exhaust giving, say, from 50 to 100 explosions per minute according to the load on that particular engine. These troubles might be modified, but could hardly be entirely abolished, by passing through silencing pits, or by carrying the outlets to a distance. Another important consideration is the rise of temperature in the engine-house. This might, however, be obviated at least to a great extent by special contrivances. But to get rid of the troubles from exhaust, and from radiation of heat, simply means increasing the initial outlay. With regard to this initial outlay, the engineer's estimate is that the generating plant for the preliminary installation will cost, with steam £2,700, and with gas, £3,092. This shows a balance of £392 in favour of steam. In the complete installation the cost for generating plant is, with steam, £13,325, and with gas, £17,432, or £4,107 in favour of steam. But the initial expense is hardly ever, or never, so important as the working expense; and again, the estimate is in favour of steam—being for the preliminary installation £1,108 for steam and £1,116 per annum for gas. In the complete installation the estimate £4,201 for steam and £4,440 for gas.

Our endeavour is to give and to obtain information, and in order that our readers may examine these totals we are fain to venture to give the details, and trust that by so doing we are not passing the bounds of prudential discussion. It may be taken that as a rule authors of reports do not expect details to become public property, but this question is so important to electrical engineers generally that we venture to break through the rule and be the exception.

THE PATTON SYSTEM OF STREET CAR PROPULSION.

Among the many attempts that are being made from time to time to introduce a system of street car propulsion intended to supersede the overhead trolley construction, the Patton system is one of the latest claimants for recognition. The New York *Electrical Engineer* states that it

CAPITAL EXPENDITURE.

Preliminary Installation of 160 h.p., to actuate 1,000 16-c.p. lamps simultaneously.

Steam Plant.

One steel Lancashire boiler, 28ft. by 7ft. diameter, fixed, including brickwork	£500	
Two Willans "F F S" steam-engines, driving two Siemens dynamos direct, including feeders	1,500	£2,700
Steam, exhaust, and water connections, feed-pumps and water-tanks	500	
Six-ton overhead traveller	200	
Electric instruments and connections and double set of storage batteries	1,700	2,900
Distribution service and other mains, etc., in town (compulsory district)	1,200	
Central-station buildings		2,000
		£7,600
Contingencies, etc., 10 per cent.		760
		£8,360
Add for land (electric light works site), 918 square yards		1,000
		£9,360

Dowson Gas Plant.

One Dowson gas set, including one gas-tank, two generators, scrubbers, etc., fixed	£732	
Two Crossley gas-engines, 35 h.p. nominal each	1,200	
Two Siemens dynamos, belt driven, all fixed	710	£3,092
Water tanks, piping, and connections	100	
Six-ton overhead traveller	300	
Electrical instruments and connections and double set of storage batteries	1,700	£2,900
Distribution, service, and other mains, etc., in town (compulsory district)	1,200	
Central-station buildings and generator sheds		2,000
		£7,992
Contingencies, etc., 10 per cent.		799
		£8,791
Add for land (electric light works site), 918 square yards		1,000
		£9,761

CAPITAL COST.

Complete Installation, 1,400 h.p., to actuate 10,000 16-c.p. lamps simultaneously.

Steam-Driven Plant.

Four steel Lancashire boilers, 28ft. by 7ft. diameter	£2,200	
Three Willans "F F S" steam-engines driving three Siemens 45-kilowatt dynamos direct		
Three Willans "II S" engines, three Siemens 150-kilowatt dynamos	10,825	£13,325
Two Willans "III S" engines, two Siemens 200-kilowatt dynamos		
Foundations, etc., to above	300	
Steam, exhaust, and other connections	1,000	
Water-tanks, feed-pumps, etc.	550	3,130
Overhead traveller, feed-water heaters	1,080	
Fuel economiser	500	
Electrical instruments and connections, and two double sets of storage batteries		5,300
Distribution service, etc., in town		9,800
Central-station buildings and chimney		3,700
		£35,255
Contingencies, etc., 10 per cent.		3,525
		£38,780

consists essentially of a combination of gas-engine, electric generator, storage battery, and motor, all carried on one car. The arrangement is shown diagrammatically in the accompanying figure.

The chief point of merit claimed consists in the employment of a storage battery so arranged as to be capable of being charged continually by the generator, which from the intermittent character of the load can be of considerably less capacity than would be required were the power of the

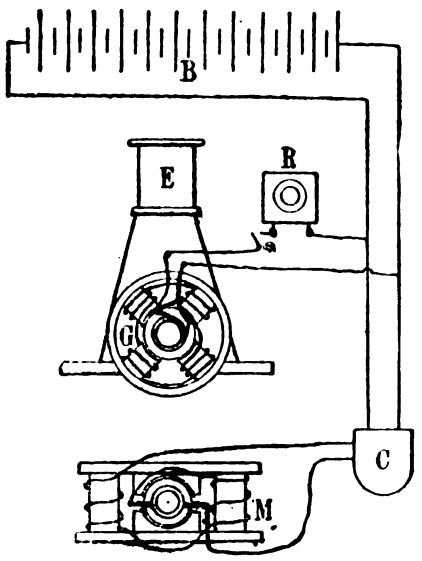

Diagram of Circuit in Patton System.

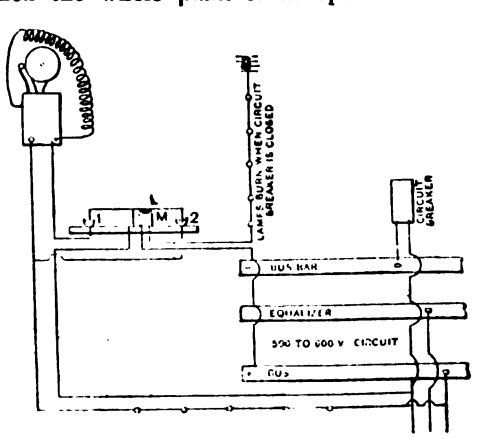
engine to be applied to the car axle direct. In the diagram, E represents a vertical gas-engine, coupled direct to the shunt-wound dynamo, G; a battery of accumulators is shown at B, and the motor is represented at M. The controller is shown at C, and R is the starting rheostat.

A car equipped with a combination of this kind has been in operation on the Calumet Electric Railway line in Sixty-seventh-street in Chicago for several weeks, and is reported as giving general satisfaction. The operating expense is said to be about one-half that of running a trolley car of the same capacity.

A TELL-TALE FOR CIRCUIT BREAKERS.*

BY E. M. HIGHLANDS.

I have on two different occasions found in central stations operating both railway and lighting circuits, with only one man who attends both to engines and dynamos, that when the whole plant is in operation the circuit



Tell Tale for Circuit Breakers.

breaker often blows out without the engineer hearing it, and, consequently, often remains open quite a while. The superintendents of these plants generally try to cut expenses, and object to installing any apparatus that is not absolutely necessary, and on these occasions, for an outlay of 8dol. to 10dol., I have been able to place the following alarm on the circuit, which rings a 7in. gong while the circuit breaker is open and the instant it is closed immediately ceases to ring, and it does this without the use of batteries or any attention whatever. I think the diagram herewith will be almost self-explanatory.

Two circuits are required, one on each side of the circuit breaker—one to ring the bell, and the other to operate the switch. The operation is as follows: The magnet, M, attracts a pivoted lever, L, which completes a circuit through a cup of mercury, 2, which cuts the bell out. When the circuit breaker opens, the magnet releases the lever, L, which makes contact through cup 1, and consequently rings the bell, which has a 7in. gong. A shunt of 100ft. of No. 30 wire from the negative binding post to the vibrator post prevents sparking at the bell contacts. I think this scheme is in use in several Iowa stations, having been seen and approved of by visiting electricians.

AN OPTICAL PHASE INDICATOR AND SYNCHRONISER.*

BY GEORGE S. MOLER AND FREDERICK BEDELL.

The following instrument has been devised by the writers to give definite information in regard to the relative speeds and phase positions of the motor and generator in laboratory investigation. It shows:

1. When the machines are synchronous.
2. Which machine is running the faster when they are not synchronous.
3. The angle by which the motor lags behind the generator.

We will first describe the simplest form of the phase indicator. The motor and generator are placed together with shafts in line and abutting, but not quite touching. The two machines must have the same number of poles, so that a revolution of the armature of each represents the same number of alternations. The abutting ends of the shafts carry two discs, one connected rigidly with the motor armature, the other similarly connected with the armature of the generator, as shown in Fig. 1. In these discs are curved slits, one slit for each pair of poles of the machines. These slits are shown in Fig. 2 for an eight-pole machine. The two discs are in every way similar, the one being the reverse of the other. The two discs are practically superimposed, and together form one disc with four holes, where the slits of one disc cross over the slits of the other. Evidently the distances of these four holes from the centre depend upon the relative positions of the two armatures; they move in and out as the armatures shift their relative positions. From the symmetrical arrangement of the slits, if one armature is stationary and the other is moved past two pole-pieces or through 90deg. of arc (corresponding

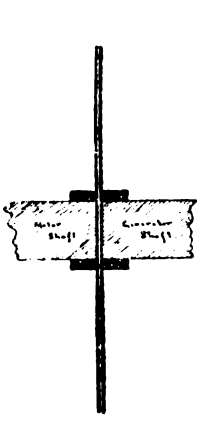


Fig. 1.

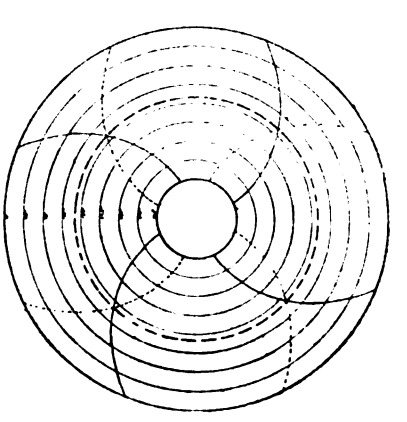

Fig. 3.

to a complete period of alternation, or 360deg. of phase), the intersection of the slits will be the same distance from the centre as before. The curvature of the slits is such that the distance to or from the centre that the intersections of the two sets of slits move is proportional to the change in relative position of the two armatures.

* The *Electrical Engineer* (New York).

* Abstract of paper presented at the Philadelphia meeting of the American Institute of Electrical Engineers.

Digitized by Google

When the two armatures are running at the same speed in the same direction and there is a source of light on one side of the discs, the intersection of the slits, as seen from the other side, appears as a continuous ring of light. A slight difference of speed causes this ring of light to move outward or inward, according to which disc is revolving the faster. The more rapidly the ring moves in or out, the greater the difference in speed of the two discs. If the ring is moving out, a new ring starts at the centre when one ring reaches the edges, and these rings keep following one another outward. If the difference in speed is the other way, the successive rings move inward.

In Fig. 3 the heavy dotted line represents the ring of light for a particular position of the two discs.

The position of the ring of light indicates the relative position of the two armatures. The discs may be secured to the shafts, so that when the armatures are in the same positions with reference to the pole-pieces (*i e.*, the machines are in the same phase) the ring of light will be at the inner or outer ends of the slits. The concentric rings in Fig. 3 represent the phase differences corresponding to positions of the ring of light in this case.

For convenience in operation, the arrangement of the apparatus, which has thus far proved satisfactory, has been as follows: On one side of the pair of discs is placed an incandescent lamp enclosed in a box. One side of the box is close to the discs and has a slit in it about ½in. wide, extending from the shaft to the circumference of the disc.

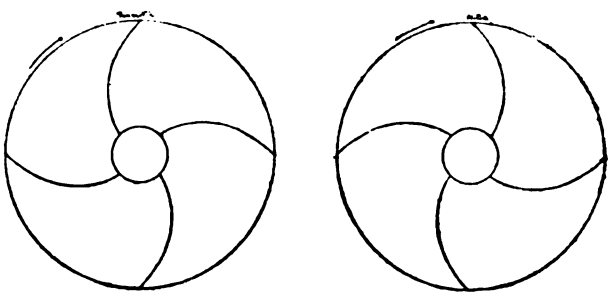

Fig. 2.

This slit is covered with a piece of oiled paper, so as to give a diffused light upon the discs. A complete ring of light is no longer seen from the other side, but only a small portion, corresponding to the width of the ½in. slit. A stationary scale is fixed so as to extend from the shaft to the edge of the discs on the opposite side from the lamps, so that the distance of the changing line of light from the centre may be read so as to give the phase difference of the two machines by direct reading. To enable one to see the scale and line of light most conveniently a mirror is arranged at 45deg. with the discs, so that the line of sight is at right angles to the shaft.

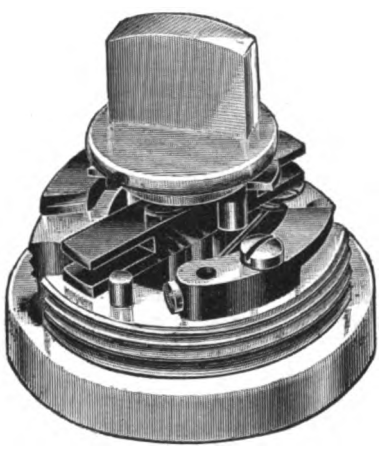
The discs may be arranged in the manner just described upon the abutting ends of the motor and generator shafts only in case the two machines have the same number of poles. Where such is not the case one or both of the discs can be driven by gears, which will give the proper relative speeds of the two discs.

In operation the instrument has proved quite satisfactory, giving exact and definite information concerning the changes in the armature lag of the motor. The fluctuations in this lag are usually quite marked, and the conditions which cause them can be readily investigated by this apparatus. For instance, this fluctuation is small with proper field excitation. As the field current of the motor is diminished, this fluctuation increases, the line of light moving rapidly back and forth through a greater and greater distance, which finally becomes so great as the excitation is weakened that it goes a distance beyond which it cannot recover—*i.e.*, the motor gets out of step and stops. It would be possible to make a more detailed investigation of these fluctuations by means of a revolving mirror, and they may be photographed and made of permanent record by means of a moving plate.

The apparatus can be applied to other lines of work involving an investigation of phase differences and synchronism, and may be modified to meet the requirements of the problem in hand; but it is peculiarly suited for use in synchronous motor work, for which it was designed. The scope of the present paper admits only of a general description of the apparatus here given.

WARD'S DOUBLE-BREAK QUICK-ACTION SWITCH.

In the annexed illustration is shown the double-break quick-action switch manufactured by Messrs. J. H. Ward and Co., of the Gorton Brook Electric Works, Manchester. This switch has few working parts, and is said to be permanently reliable and cheap. The advantages claimed for this switch, which is mounted on porcelain, with cover and handle of the same material, are in the construction of the terminals and in the cross-bar, which, instead of entering between two contact-plates, grips from the outside a solid tongue of metal cast on to the terminals. By this means sparking is reduced, and the faulty contact caused after a little usage by the softening of the spark-plate, in the ordinary type of switch, is said to be entirely done away with. The metal conducting parts are massive, and are fixed to the front of the base. The spring, instead of working on the brass current-carrying parts, works on two steel pins, thus reducing friction and the wearing away of parts where the spring usually rubs. The switch is rendered dustproof by the method of fixing the handle to the cover. This type of switch



is made in sizes of from one to six amperes, and from six to twelve amperes.

THE HISTORY OF WOODHOUSE AND RAWSON UNITED, LIMITED,

As Detailed in the Bankruptcy Court.

THURSDAY.

The resumption of this enquiry took place yesterday, when **Mr. Lambert**, liquidator of Woodhouse and Rawson, Limited, was examined by the Official Receiver. The witness stated that he supposed that the prospectus of the United Company came before him as a director of Woodhouse and Rawson, Limited. The managing directors did most of the work in connection with the valuations. He always understood that the patents were valuable, but no value had, so far as he knew, been placed upon the patents. He was not an expert as to electrical patents. The Woodhouse and Rawson Company had only been in existence two years when it was absorbed by the United Company, and it had, in fact, only been able in that time to begin to get to work.

By **Mr. Pilling**: The witness had nothing much to do with the estimate of £75,000. He knew the estimate was made, but not exactly how or by whom. As a vendor he, of course, accepted the estimate. He could not recollect what went to founders' shares at the distribution. Out of the £75,000 received, £51,000 was in debentures and £12,000 in cash, and four-fifths, or, roughly, £40,000, in debentures went to the founders' shares, or should have gone had it been possible to realise them, but he thought that the founders' shares did not, in fact, realise anything.

By the **Official Receiver**: A sum of £17,000 guaranteed book debts was wiped out. Mr. Rawson was given £10,000 for special services in connection with the Elmore business, out of which they had done very well. He did not think that Mr. Rawson was paid anything for the promotion of the United Company.

By **Mr. F. Rawson**: As to valuations he knew little. As to his own knowledge, the managing directors prepared the prospectus. He did not instruct valuers, nor did he know of any minute of the Board as to value. He thought there was a good future for the Cadby Hall Works. He agreed that many differences arose between Mr. Rawson and Mr. Hoster over the negotiations at the formation of the United Company, Mr. Rawson doing his best for the United, and Mr. Hoster for the Limited. Great care was taken by the directors of the United Company to get all information

Digitized by Google

possible. Mr. Rawson tried all he could to get a settlement with the holders of founders' shares.

Mr. Philip Rawson, who was examined by the Official Receiver, said he was no relation to Mr. F. Rawson. He first lent money to Mr. F. Rawson, and afterwards became a director of the manufacturing company. He was not interested in the formation of Woodhouse and Rawson, Limited, from the partnership. He was not paid the money lent to the partners, but it was probably settled by getting shares in the company. The witness said that he did not press for his money, or enquire into the affairs of the partnership, and he had no recollection of getting Mr. Pixley's report. He was not aware of a final deficiency of £44,000 of the manufacturing company. He was an original director of the United, but did not attend the preliminary meetings, as he did not intend to become a director. He did not recollect about the valuer's original report of Mr. Edmunds not forthcoming (dated April 12, 1889). The witness did not form any independent idea of the patents, but was satisfied as to the amount to be given after discussing the matter with Sir A. Cappel. He considered the business to be taken to be both industrial and financial, so far as financial meant testing and selling electrical concerns. He remembered the minute referring to the secession of three directors and the circular to be sent to proposing shareholders. He believed he saw it in print before being issued, but thought it was brought before the solicitor. The circular did not mention anything about the return of subscriptions. He understood, however, that the circular was in accord with the minute. He would generally understand from the circular that it carried out the views of the retiring directors, but now admitted that the wording of the circular was not so in accord. He did not know the connection between Mr. F. L. Rawson, Baron Grant, and the Phœnix Trust. He did not think Baron Grant was consulted in the formation of Woodhouse and Rawson, Limited. The report on the sale of Elmore shares to the Phœnix Trust was not recognised by witness. He did not recollect the sale of Elmore shares to the Phœnix Trust, and did not think he knew anything about the Phœnix Trust at that time, or the confirmation of minutes wherein this was mentioned. The witness did not make any enquiry as to the composition of the Phœnix Trust, and did not recollect the minute promising the report of the managing director above mentioned. He did not recognise the circular dated September 1, 1890, puffing up Elmore shares, but supposed that he must have seen it. He was appointed a committee with Mr. F. L. Rawson as to the financial arrangements of the Okonite Company, but had no recollection of doing anything as such a committeeman. He did not recollect any consultation for application for Okonite shares from nominees of Woodhouse and Rawson United. The balance-sheet 1891 and financial account was for over 13 months and industrial over 11 months. He did not remember that the 13 months was to include the Epstein Company's formation. Certainly not as far as memory of the witness went. Such extensions did, however, admit of the paper profit being shown. He did not recollect any enquiry as to shares taken up by the public, and did not know that even to the present time only five Epstein shares had been taken by the public. The Epstein interest was acquired for £4,000 and experiments made with it cost £12,000—being a total of £16,000. The witness was told that the value of the Phœnix shares held by the company was £15,000, and at that time he thought this was correct. He did not remember Messrs. Pilling's report on the Manchester accounts showing a loss, or another report on the Kidsgrove accounts. He was aware that the industrial businesses in 1891 were not very prosperous, but could throw no light upon the advance of money for transactions in preference shares. It was suggested that this advance was to get a Stock Exchange transaction so as to get a quotation for shares, and the witness thought that the transaction entered into in accord with the minute of the Board was right, but he did not recollect the whole circumstances, and therefore could not say what guided them at the time. On December 3, 1893, witness wrote a letter to Sir Rawson Rawson. His resignation had been held over, and Sir R. Rawson wrote to know how the resignation was to be treated. The letter of resignation was sent in at the beginning of September, 1892, and a further letter on the subject later in the month. The circular relating to the creation of debenture stock spoke of it as a first charge, but as a matter of fact they were not secured as a first charge. Witness understood that they were a first charge on the whole property of the Company. He was not aware that some of the old debenture-holders converted this stock, and had lost their first charge by the proceeding.

Cross-examined: He was of opinion that Mr. F. L. Rawson's application for preference shares was *bonâ fide*, and he saw no objection to the shares being delivered to nominees of the managing director. Sir Rawson Rawson's statement as to the financial position of the Company might have been in 1890 and not in 1891. The witness had a total interest of £4,000 in Woodhouse and Rawson United; he had not sold a single share, and held them now.

Sir Leopold McClintock, examined by the Official Receiver, said that he held 250 shares in Woodhouse and Rawson, Limited, as security for a loan, and 40 shares in manufacturing company. He had no recollection of the large debt to Woodhouse and Rawson, Limited, or to the valuation put upon the manufacturing company. The company was wound up in 1889. The witness had received no dividends from the manufacturing company. He joined the Board in place of one of the gentlemen who had resigned, and thought that the business was to be a combination of financial and industrial—mainly industrial. His own inclination was in favour of the industrial work.

[A reprinted prospectus was here put in that gave the name of Sir L. McClintock as an original director, whereas he did not join the Board till after the date on the prospectus—viz., July 15—the list opening on July 22, Sir Leopold McClintock not joining till August.]

The witness did not know the relations of the managing director with the Phœnix Trust. He resigned on August 18, 1890, but remained a little longer on pressure being brought to bear upon him. The financial business was getting beyond him, and the work too much.

Mr. Foley, examined by the Official Receiver, stated that he was at first in the secretary's office, and that many documents of a confidential nature passed through his hands. He had no knowledge of the transactions *re* the Phœnix Trust, but became aware of some of them afterwards. He did not join the Company until October, 1890, and the circular referring to Elmore shares and the Phœnix Trust was dated September 1. There was a contract between the Phœnix Trust and Woodhouse and Rawson United to take certain shares. Witness bought founders' shares of the Elmore Company, and held them now. He became secretary in February, 1892. Letters passed between the National Finance Corporation and Woodhouse and Rawson United.

Mr. Stutchbury, examined by the Official Receiver, deposed that he was secretary of Woodhouse and Rawson United in January, 1891, and manager in the beginning of 1892. After becoming secretary he looked into the business affairs of the company and formed the impression that the industrial part was neglected, and gathered from the general manager, Mr. North, that it was conducted at a loss. In discussion with the chairman he mentioned that he thought that the industrial part had been neglected, and suggested that more attention should be paid to it. The chairman thought it better to continue the financial business, but the managing director mainly agreed with him. Then he converted Sir J. Stokes, and afterwards Mr. Pope, to these views. From extracts from the books in 1890, it was shown that the industrial businesses, except works department, each and all showed a loss; the Cadby Hall department showed a profit. So far as Manchester, Bradford, and the Jensen bell departments were concerned, the books showed the loss. He had the balance-sheet of 1891 prepared, and thought that the original draft might be at the offices of the Company. The draft showed a loss of about £15,000 on trading. The draft was taken to Mr. Rawson, but to his knowledge it was not brought to the auditor. From extracts of books for 1891 similar to those of 1890, the losses were shown.

The proceedings were then adjourned.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.

The thirty-first half-yearly ordinary general meeting of the shareholders in this Company was held yesterday afternoon at the Cannon-street Hotel.

Mr. S. William Silver, who occupied the chair, stated that the principal object for which the meeting was called was to declare a dividend for the half-year. The books were made up, as he thought they were aware, once a year, and he had no hesitation in recommending for their adoption that a dividend of 10s. per share, or at the rate of 5 per cent. for the half-year, be declared. When he met them last February he referred to the considerable difficulty they had experienced in securing contracts and work generally owing to the depression in trade which then existed. This state of things had, unfortunately, increased. Notwithstanding this condition of affairs, they had managed to get their fair share of business. This was to be accounted for by the efforts used to make known, both at home and abroad, the excellence of the work turned out at Silvertown, and the excellent condition of the machinery, which was quite up to the requirements of the hour. So much was this the case that he thought he might say they received the first offer of most of the improvements introduced into this country. With regard to submarine cable work, they had done practically very little, with the exception of laying a short line for the Spanish Government. The works at Silvertown and Persan were in a very efficient state. He did not think there was anything else of importance to which he need direct their attention, and concluded by formally declaring the dividend.

The proposition was seconded by **Mr. Abraham Scott**, a director.

At the request of the **Chairman**, **Mr. W. Grey**, one of the directors, gave a short account of his recent visit to Persan, in the course of which he stated that he found the factory there, and everything connected with it, in an efficient and satisfactory condition. He was quite satisfied with the way in which their affairs were being managed there, although of course business was nothing near so brisk as in former years.

The payment of the dividend was then sanctioned.

Wolfenbuttel-Brunswick Tramway.—An arrangement has been made between Messrs. Schuckert and Co., of Nuremberg, and Messrs. Brandes and Co., of Wolfenbüttel, for the construction of an electric tramway between Wolfenbüttel and Brunswick. The former will finance the undertaking and carry out the electrical part of the work, while the latter will lay the rails, supply the iron masts, etc.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE DANGER OF FAMILIARITY WITH DANGER.

Incidents, the fatalist would say, hardly require "improving upon": it is almost useless to moralise upon them, because no change of antecedents can be thereby effected. Until such time, however, as we deem these doctrines more worthy of credence, we intend to punctuate occurrences with comment of the kind that blends plain speaking with sympathy and regret.

The occasion that calls for such remarks as the above is that to which reference is elsewhere made—viz., the terrible accident which happened on Saturday last at the Blackfriars sub-station of the London Electric Supply Corporation's system, wherein one of their employés received the full force of the high-tension current, and was, of course, instantly killed. Since the unfortunate man was a servant of the electric lighting company, and not one of the general public who would be presumably ignorant of all danger, there is in this accident no scope for the daily Press to make much of it by headline or editorial. The gas journals, we should say, will hardly venture to criticise this mote in the eye of electricity, seeing that the countless endeavours of authorised gas-fitters to find leakages of gas with a lighted candle prove the presence of a big beam in their own. It falls, therefore, upon the electrical Press more especially to analyse the causes of such a terrible incident as this, and apportion the blame or responsibility where it is best deserved.

Summarising the evidence, and gauging the probabilities of the case, it seems quite clear that *if* (such virtue is there in an "if") the deceased man had replaced a guard rail he might yet have been alive. Yet one can hardly say that he was to blame; this particular combination of circumstances had never arisen before, and could hardly have been specially contemplated or provided for in any way. The accident shows most of all the immense and absolute importance of taking every possible precaution at all times in such work, and yet the tendency of human nature is continually towards fatal forgetfulness—the one little slip which makes life the forfeit. There is no cultivating a habit of carefulness by personal experience in this case: once trespass too far and all is over. The same thing happens time and again in other directions: a collier strikes a match to light his pipe, and forthwith the whole pit is fired; he may neglect the roof-timbers in the place where he works, but pays the penalty when the heavy stones fall down and crush out his life. The abstract danger of a familiarity that breeds contempt is less carefully avoided by the average worker than is the actual object itself which contains the hidden terror.

It would be illogical to declaim against high tensions as a result of this accident; we live in an age of high pressure, and must fall in with the spirit of the times. For that matter, a pressure of ten thousand volts on an alternating-current circuit offers no more danger to the unfortunate being who enters into the circuit than does one or two thousand. Either of them is more than sufficient to destroy life in the merest fraction of a second. The question may, how-

Digitized by Google

ever, well be asked, how it is that the fatal accidents occurring in electricity supply station work have so far taken place on the higher pressure systems? We believe that hitherto at the Bankside, West Brompton, and other stations worked on the two thousand-volt standard, there have been no accidents whatever of a similar nature to that now dealt with. The reason for this does not lie, as above stated, in any quantitative difference in pressures: it is, we think, to be sought rather in the extraordinary care taken on every hand in these stations to enclose and protect the high-pressure circuits. The chamber in which operations like those carried on by the deceased man must be conducted, ought to be arranged on the presumption that dangerous elements will tend to come together. Ample space should be allowed for any operations required, and the points of contact or terminals of high-pressure mains so covered up and protected that ordinary methods will not permit any employé to touch them. This can quite well be done, whilst at the same time preserving full efficiency and convenience in the station plant.

And yet it is difficult to say that the electric supply company absolutely deserves blame. Most elaborate precautions are taken, as will be seen from the account on another page, to secure the safety of the employés from contact with "earth," and the engineers would naturally find it hard to believe that part of a man's body should actually take the place of a switch bar—some eighteen inches long—fenced off on all sides. This is just what happened, however, and, of course, it might under the same conditions occur again. We prefer to think, however, that no more such terrible incidents will be recorded in the annals of this station, and that it will in the future be impossible—as nearly as may be, that is—for any of the workmen to receive a fatal shock unless they are on suicide bent. Even then it should require an act of wilful damage to the plant in order to obtain suitable conditions.

Some of our readers will doubtless know the Blackfriars station. If so, they will share our admiration of the switching equipment and general station appliances in the transformer-room. Arrangements equally good for the switch-room, in which this accident happened, ought to secure safety as far as it is possible to obtain it; but when all is said and done, the element of human fallibility yet remains. Not all the Board of Trade rules in the world can prevent a sleepy signalman from sending a crowded express train to its doom in the rear of a shunting goods train; in the present case, however, the unfortunate man himself was the only victim.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

"OUR REVIEW OF REVIEWS."

SIR,—I was unable to give you "Our Review of Reviews" last week, my free copy *not* having reached me. Sam says this is not surprising, considering the number It prints for gratuitous circulation. I believe there is some truth in this. For instance, one day when I went to Its office to buy a copy—the day after publication—the lady editress informed me that they had had a run on that issue—the usual publisher's excuse for not speaking the truth. The lady, however, ultimately managed to supply me with a copy that had been returned through the post. Sam says he thinks It is revising Its free-list; but as he still receives three copies he made me a present of one, and here I am. Turning up It of June 21, I find it stated that this is the last number which will be published. Well, nobody will weep. But reading on further, I find that it was merely the last number that would be issued from 11, Queen Victoria-street. Atcheu! The next issue was, It stated, to blossom forth at 117, Bishopsgate-street. This address, Sam remarked, on looking up the directory, is the home of the House-to-House Electric Light Supply Company, and also the late business address of Mr. R. Hammond. Of course, there is no connection between the two. "Gas Meter," I am pleased to say, admits candidly that "'E dunno where 'e are," and trots out a bit of schoolboy's Greek. Then follows a reference to the competition for self-contained vehicles, which you mentioned in March. Better late than never. Something next appears from an American source about electric head lights. Surely a "meteor" is sufficient for the purpose. Following this comes a lot of twaddle concerning the City of London Company's recent banquet, and an article by Mr. C. P. Sparks on transformers is given. Passing on from "Our Review of Reviews," which this week is scarcely worth mention, It gives a supplement describing the central station at Burton-on-Trent, which was detailed in the *Electrical Engineer* on June 8. Mr. Chestnut, jun., manages to fill three columns from the financial dailies, and "Lamplighter" pads out with some five columns of Press cuttings, interpolated with "I this and I that and I the other." Pheugh!

I shall soon begin to think that "Gas Meter" is a Frenchman. He writes quites nicely in It of the 28th June about the French Anarchists and the late President Carnot; and this, too, in a *soi-disant* electrical sheet! "Gas Meter," it appears, was present at the recent assembly of the Asso ciation of Municipal and County Engineers. So was Mr. Hammond. Do you see? American gas commissioners, the *Century* on municipal spirit in Germany and coal tar conclude this interesting hash up. An article follows by Mr. J. S. Raworth descriptive of his patent switch and safety gear. The Doulton casing for underground cables, which you illustrated and described several months ago, is now discovered by It. Then comes that would-be-if-you-could-know-all padding called "Our Review of Reviews." It is not so silly as it used to be. It has got frightened; It does not like being treated in the same manner as It deals with others; but It is rot. It will find it warm if It goes to see H. L., whose identity It has failed to discover; being sheet lightning It ought to be already pretty near. Passing on from Mr. Chestnut, jun., a note is given on electric tanning; that's what It is going to receive. But stop. The information contained in this note was published in the *Electrical Engineer* months ago, and now It states that "we have been favoured with a report," etc. "Lamplighter" then holds forth with the usual supply of paste and scissors set forth in the first person, the information contained in the whole of which has already been published in your journal. Sam says that next week I must make it very hot for It. I will.—Yours, etc.,

Timbuctoo, July 3, 1894. JOHNNY.

REVIEWS.

Electric Light Installations—Vol. II.: Apparatus. By Sir DAVID SALOMONS, Bart., M.A. London: Whittaker and Co.

The first volume, of which the present work forms a continuation, has passed through several editions, and this fact alone will tend to draw attention to the book under review. It gives essentially a description of the plant and accessories used in electric light installations—the foremost types of dynamos, motors, and apparatus being dealt with.

Digitized by Google

Of course, to have referred to each individual one would have rendered the book merely an illustrated catalogue, which was not the author's intention. The author has not confined himself to mere descriptions, but has given much information of practical value in the working of electric lighting plant. Whilst some instances are given of the applications of electrical energy, the author has decided to treat the special applications of the machines and appliances in a third volume, which, when completed, might readily be amalgamated with Vols. I. and II. so as to form one book.

L'Eclairage a Paris. Par HENRI MARECHAL, Ingénieur des Ponts et Chaussées et du Service Municipal de la Ville de Paris. Paris: Baudry et Cie., 15, Rue des Saints Pères.

The present work comprises a volume of 500 pages with 211 illustrations in the text. It gives a full description of the different methods adopted in the lighting of Paris, and detailed particulars of this important service. Most of the chapters are, of course, devoted to the subjects of the production, distribution, and utilisation of gas and electricity. The gas industry is represented by the Compagnie Parisienne des Gaz, which employs over 9,000 persons, and distils per annum more than a million tons of coal. The gas is distributed not only in Paris but also in the suburbs through mains extending over a total of 1,500 miles. The electric lighting industry has made striking progress, various companies having been authorised to supply electrical energy. The town of Paris itself, as will be remembered, has set an example in erecting municipal plant at the Halles Centrales. M. Maréchal's work shows that if all the gasworks are more or less alike, there is great variety in the different systems employed in the large electric lighting stations. The production of electricity is described under its different forms—namely, continuous and alternating currents, and distribution direct and by means of accumulators. The great diversity in the distribution of electricity is very instructive, and permits of useful comparisons being established. A chapter is devoted to the distribution and sale of electricity, cost and sale prices being given. The relations of the Municipality with the gas company and the electrical companies are clearly and carefully explained. An interesting chapter deals with the calculation of the lighting of the public roads, showing the influence of the height of the lamp-posts, and giving diagrams of the photometric curves of the different lamps and burners in use. M. Maréchal's work will prove interesting to those concerned in the electrical illumination of large towns.

ANOTHER FATAL ACCIDENT AT BLACKFRIARS.

We much regret having to record another lamentable occurrence at the Blackfriars sub-station of the London Electric Supply Corporation. Last year, it will be remembered, one of the company's employés at this important station received a fatal shock, owing to an act of carelessness in his not having switched off one of the high-tension mains—a duty which he well understood and which he had carried out scores of times previously.

On the present occasion the exact circumstances have been somewhat different, though in the end it is much to be feared that the same want of constant watchfulness and care on the part of the workman may have been the proximate cause of the sad accident. On Saturday afternoon last, about half-past four, the unfortunate man was engaged in the underground chamber where the high-tension mains enter the station from Deptford, and thence are connected by means of switches to the Blackfriars transformers, or to those at the other sub-stations belonging to the company—in all of which, it will be remembered, the 10,000-volt current is transformed down into one of a pressure equal to 2,400 volts.

The chamber itself, where the connections between the machines at Deptford and the London mains are thus made, is quite a small room—perhaps too small for such important work to be carried on; but it is safe to say that the circumstances giving rise to this accident will hardly arise in the future. On each side of the room are placed the inner conductors or positive wires of the Ferranti concentric mains coming from Deptford, and terminals or contact-pieces on these wires are connected with similar terminals or contact-pieces on the outgoing leads—placed on the wall underneath—by means of switch bars pushed in from the centre platform. Each set of terminals is separated from its neighbours alongside by means of heavy slate partitions, and guarded in front by a substantial wooden handrail, which slides up and out when testing goes on.

This appears to have been the case on Saturday, as the deceased man had removed the handrail in front of the third London main, in order to test for a fault. Without replacing the handrail, he then turned to the other side of the chamber to connect with a dead main, but while doing this his head must have touched the live main placed on the wall just above. The shock from this contact (though of course no current passed through his body then) appears to have knocked him backwards across the platform—in the absence of the handrail—right on to the terminals, where he had just been testing. The circuit was then practically completed from head to back where he was in contact with the terminals, and the full force of the high-tension current followed.

The fuse on this main at Deptford was at once blown out by the rush of current, and by the time that help arrived (the unfortunate man's assistant was only a few yards away), the body was released from contact, but, of course, death had been instantaneous.

It seems quite certain that no "earthing" occurred in the case at all: the centre platform on which the man stood is covered with thick sheets of indiarubber; it is formed of well-varnished wood, and supported on a number of oil insulators. Moreover, the man was wearing the usual thick indiarubber-soled shoes, which are not punctured in any way. The explanation we have given, however, seems quite clearly to be the most accurate possible: the "charging" shock threw the unfortunate man into such a position—owing to his having forgotten to replace the handrail—that his body short-circuited the mains, with, of course, fatal results.

SOME STORAGE BATTERY PHENOMENA.*

BY W. W. GRISCOM.

The study of a complete curve of discharge of a storage battery discloses three rather sharply defined changes in potential difference, and after allowing for the effect of internal resistance, we find that the changes are those of the E.M.F. What is the reason for these changes? Which plate is responsible for them?

A microscopic examination of the negative (spongy lead) plate disclosed metallic lead and what appeared to be one or possibly two sulphates. The positive (peroxide) plate, however, showed spongyform crystals of very dark colour, known as electrolytic peroxide; other comparatively large crystals of brilliant red, probably Frankland's red sulphate; others of yellow, probably yellow sulphate; and, finally, the better known white sulphate of lead.

The production of these diverse chemical forms must be attended by production of diverse potentials, and the E.M.F. of the battery is possibly a resultant with one or more chemical reactions predominating at various parts of the charge and discharge.

That there should be any change of E.M.F. during the charge or discharge of the battery shows the complexity of the chemical actions, and as the changes are at times sudden and at times gradual, uniform and invariable, it would seem to point to the conception that the E.M.F. is the resultant of three or more sets of chemical actions.

The material on the charged positive plate of the battery is commonly called peroxide of lead, but it certainly differs from it both in its ability to generate E.M.F. and in its appearance, and Fitzgerald has pointed out that its composition corresponds to the hydrated peroxide of lead

* Paper read before the American Institute of Electrical Engineers.

Digitized by Google

($H_2Pb_2O_5$). He further intimates that a higher oxide of lead may be present, such as perplumbic acid ($H_2Pb_2O_7$). McLeod has told us how peroxide of hydrogen, ozone, and persulphuric acid are produced. Then there are the two new sulphates of lead. With this array of chemical products to assist our imagination, the wonderful curves of E.M.F. of a storage battery on charge and discharge become comprehensible. And the fact observed by Gladstone and Tribe that 34 per cent. more of oxygen was absorbed by the positive plate than could be accounted for by the production of PbO_2 becomes explicable. It has probably been used in converting $H_2Pb_2O_5$ into $H_2Pb_2O_7$. Their suggestion that it was absorbed by local action between the grid and the peroxide during charge is utterly untenable. There is no such action. And if there were, the grid would not last through a dozen charges.

The conversion of $H_2Pb_2O_5$ into $H_2Pb_2O_7$ would account for the abnormal rise of E.M.F. at the end of charge, and if it be assumed that the $H_2Pb_2O_7$ is not stable but yields ozone gradually, thus accounting for the odour of a freshly-charged positive plate, it would account for the steady fall of E.M.F. on interrupting the charging current. The chemist will easily see relation between these reactions and the presence of peroxide of hydrogen and the continual evolution of oxygen from the positive plate, and the fact that a charged cell gradually loses its charge, maintaining for days a higher temperature than the air.

I am sorry that the time allotted me for the preparation of this paper did not admit of the preparation of curves showing the differences in temperature between certain plates of a cell and even between different parts of the same plate. Of course, these changes, many of them, are very minute, and they are due to at least two causes—viz., the liberation or combination of sulphuric acid on the one hand, and C_2R on the other.

In order to study the progressive changes on either plates and to plot them out in a curve, it is merely necessary to choose a substance which produces a measurable E.M.F. with the plates independently of the E.M.F. which is being produced by the two plates appertaining to the battery; but this substance must be one which is neither modified by the electrolyte nor by the minute current which it is required to produce for the voltmeter. The last is of more consequence than is generally understood, as a storage battery which has been over-discharged and which has been allowed to recuperate will, even if it be of large size—say, of 350 ampere-hours' capacity—produce a deflection on a Weston voltmeter (of about 300 ohms), which at first may be $1\frac{75}{100}$ volts, and which will immediately begin to fall with a velocity quite appreciable to the eye. Many substances have been tried for such a test plate, as, for example, zinc, carbon, platinum, and copper, but nothing seems to be better than a well-charged Faure or Planté couple of considerable dimensions. The use of such plates was first published by Mr. Crompton, although they have been used for years in my laboratories, and give concordant results.

It might be desirable, but it is not necessary, to ascertain accurately the exact fraction of the total E.M.F. which is due to the plate under test. It is important, however, to know the rate of its change of E.M.F. while the cell of which it forms an individual part is discharging or charging.

The negative plate maintains a nearly horizontal line until the potential difference of the couple on discharge has fallen to 1·9 volts, while the positive plate maintains a curve almost parallel to that of the cell, showing that the characteristic curve on discharge of a storage battery with plates of nearly equal capacity is due mainly to the reaction in the positive plate.

At the end of the charge, however, the characteristic curve of E.M.F. is due to the negative, the rapid rise of its curve being nearly parallel to that of the battery, while the rise of potential of the positive is nearly a straight line, which, however, is gradually rising.

It should be noted that this curve is the true E.M.F., and is not dependent on the internal resistance of the cell, which reaches the maximum shortly after the fourteenth hour in this case, and remains quite constant during the remaining seven hours of the charge. But while the E.M.F. is not dependent on the internal resistance, the sudden changes in each curve are usually simultaneous, indicating a common cause.

It may be considered proven, therefore, that in a storage battery with plates of nearly equal capacity, the changes in the positive plate determine the characteristic curves of potential on discharge, and that the changes in the negative plate determine the characteristic curves of potential at the end of the charge.

(To be continued.)

THE PACIFIC CABLE QUESTION.

The following letters, taken from the appendix to a Canadian Blue-book recently published, tell their own tale. Sir John Pender in this controversy has followed the devious paths of the weather-cock. At one time he blows hot, at another time he blows cold—probably because the situation is of a duplicate character; and sometimes he feels master in one direction, and sometimes in another. It is evident, however, whether the Pacific cable be laid—as assuredly it will be laid—or strangled for a time—as just now Sir John would like it strangled—he is playing his cards so as to try and remain Vicar of Bray. We like a man who knows his own mind and sticks to it, but the man whose whole policy is shilly-shally is a repugnant character to those who like to go straight at the goal when it is in sight:

Letter from SIR JOHN PENDER *to* MR. SANDFORD FLEMING.

The Eastern Extension, Australasia, and China Telegraph Company, Limited,
Winchester House, 50, Old Broad-street, London, E.C.,
July 22, 1890.

Dear Mr. Sandford Fleming,—I have read your circular letter of the 18th inst., together with the annexed correspondence with the Colonial Office, on the subject of the recent unfortunate interruption of telegraphic communication with the Australian colonies, and the establishment of an alternative route *vid* the Pacific, and if the various Governments interested are determined to have a line across the Pacific, and are prepared to incur the requisite expenditure for the purpose, I am quite ready, as I have always told you, to co operate in carrying out the work on fair and reasonable terms, and in this way the object might be attained more easily and economically than if third parties were employed. But if it should be decided to establish a Pacific communication as a separate and distinct undertaking from the existing lines, it must not be forgotten that two cables across the Pacific will be required, which, according to your own figures would cost £3,600,000, or £108,000 per annum, as one line could no more be relied upon in the Pacific than in the Java Seas, where all our three cables between Java and Australia were suddenly and simultaneously interrupted by earthquake a few days ago.

Fortunately, however, this is a very rare occurrence, only one previous interruption of the kind having occurred on our system during a period of over 20 years. Moreover, the Java Seas are mostly shallow, so that repairs can be easily and promptly made, as in the present instance, while the Pacific Ocean is not only subject, perhaps, in a greater degree than the Java waters to volcanic disturbances, but the depths are so great that repairs would be most difficult and costly when an interruption occurred. The cost of maintaining the present system amounts to over £100,000 per annum.

I am looking forward, if spared, to visiting Hong-Kong next year, travelling through Canada by the Canadian Pacific line, when I hope to inspect that wonderful undertaking in which you have played such a prominent part, and at the same time discuss with you the best means of establishing closer telegraphic communication between Canada and the Australian colonies when the time is ripe for carrying out the work.—Faithfully yours,

JOHN PENDER.

P.S.—Your letter to Lord Knutsford ignores the fact that there is at present an alternative line to India *vid* the west and east coasts of Africa, quite independent of the Red Sea route.

Letter from MR. SANDFORD FLEMING *to* SIR JOHN PENDER.

17, Victoria-street, London, S.W., July 24, 1890.

Sir John Pender, 50, Old Broad-street, London.

Dear Sir John,—I received late last evening your favour of the 22nd, and desire to thank you for it. I am very glad to find you are coming to realise that it is absolutely necessary to have an alternative cable to Australia by way of Canada and the Pacific. I have always held, and I now hold, that the means taken to establish the new telegraph connection is entirely secondary, provided that the new line be secured. Its establishment, by whatever means, is the primary consideration, and it is for the Governments concerned to decide how it is to be done. In my humble judgment, if they consult economy and decide to secure cheap telegraphy, they will act wisely in making the work a public undertaking, and in retaining it in their own hands under an efficient management.

I notice what you say about having two cables across the Pacific

Digitized by Google

on account of possible interruptions, but it seems to me this conclusion on your part is scarcely logical if as you say interruptions are so exceedingly rare. A breakdown once in 20 years would not of itself justify the laying of a second cable at an additional cost of £1,800,000.

Are you, however, quite accurate? Is it the case that interruptions on your cable are so infrequent? I have a list before me by which it would appear that the Eastern Extension cables between India and Australia have broken down 36 times within the last 18 years, and of these 14 breaks were between Port Darwin and Banjoewangie, the nearest sections to Australia. I notice also that one of the 14 breakdowns referred to caused an interruption of four months, and another of three months and a half. The other interruptions were generally for much shorter periods. It is quite true that you have now more than one cable on that section, but I do not see that duplicating, even triplicating the cable on the same route is an absolute security from interruptions as shown by the simultaneous breaking down of all three cables for a period of 10 days during the present month.

Be all that as it may, my contention is simply that a line from Australia to England by way of Canada would be a great advantage all round. That to Australia and New Zealand, it would be better than relying wholly on the one existing route. To these colonies it would give two strings to their bow, and that is commonly held to be an advantage. You say that under certain circumstances two cables across the Pacific will be required. In this I am not disposed to disagree with you, as I believe more than two will eventually be required, but let us have one at a time, and the sooner we get that one the better. In after years other cables can be laid as they are required to meet the demands of a wonderful development of commerce, which I am satisfied will come in the not distant future.

You suggest that repairs in the deep water of the Pacific would be most difficult and costly. Let me remind you of the fact, established by experience on the line between Lisbon and Pernambuco, passing through waters about the same depth as the Pacific, that no repairs of any consequence have been found necessary in the deep-water section of that line since it was laid some 13 years ago.

Referring to the postscript of your letter, there is indeed a cable laid round the west and east coasts of Africa connecting England with Aden in that way, but that line of cables passes through no less than 10 foreign ports, beginning with Lisbon and ending with Mozambique. You are aware, too, the existence of that line did not obviate the necessity, so recently as the month of May lost, of sending Australian messages through Russia Siberia, China, and French Cochin-China, when two of your cables east of Aden broke down. I still think I was strictly correct in my statement to Lord Knutsford respecting the proposed Pacific cable: "It will indirectly give a new means of communication with India should the lines through Europe and the Red Sea become through war or other cause unusable."

Receive my thanks for your friendly letter and for the evidence it conveys to my mind that you are prepared to accept the conviction that Canada and Australia must be connected telegraphically. In this you merely evince your usual wide discernment, and few men have it in their power in a larger degree than you to hasten the advancement of a public undertaking fraught with so many advantages to the colonies and the Empire.—Yours faithfully,

SANDFORD FLEMING.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

The proposals contained in the provisional orders included in the Electric Lighting Provisional Orders (No. 4) Bill have been published in an official paper, of which the following is an abstract.

Aberdare Electric Lighting Order, 1894.—The undertakers are J. C. Howell, Limited. The area of supply is a portion of the district of the Aberdare Local Board. The order contains provisions that the undertakers shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions; also for the appointment, remuneration, and duties of electric inspectors, and the testing of electric lines, and other works.

Birmingham Electric Light and Power Order, 1894.—The undertakers are the Birmingham Electric Supply Company, Limited. The area of supply is a portion of the city of Birmingham. The order contains provisions similar to those referred to in the case of the previous order. The order also provides for the revocation of the Birmingham Electric Light and Power Orders, 1889 and 1891.

Chelmsford Electric Lighting Order, 1894.—The undertakers are Crompton and Co., Limited. The area of supply is the borough of Chelmsford. The order provides for the supply of electrical energy by the undertakers in the whole of the area of supply on certain specified conditions. The order also contains provisions similar to those referred to in the case of the Aberdare Electric Lighting Order, 1894, above mentioned. The order also provides for the purchase of the undertaking by the local authority after the expiration of 21 or 31 years from the commencement of the order on certain terms specified in the order; the transfer of the undertaking with the consent of the Board of Trade and the local authority to the Chelmsford Electric Lighting Company, Limited; and the revocation of the Chelmsford Electric Lighting License, 1890.

Guildford Electric Lighting Order, 1894.—The undertakers are the Holloway Electricity Supply Company, Limited. The area of supply is the borough of Guildford. The order contains similar provisions to those referred to in the case of the Aberdare Electric Lighting Order, 1894. The order also provides that the local authority may purchase the undertaking after the expiration of 35 years from the commencement of the order.

ELECTRIC LIGHT AND TRACTION BEFORE THE ASSOCIATION OF MUNICIPAL ENGINEERS.

In our last issue we published the paper read by Mr. Shoolbred before this association on the "Bradford Corporation Electricity Supply." The illustrations showing the ampere output curves were printed not quite in proper order, but, nevertheless, our readers have no doubt been able to understand the correct arrangement. We now give, as promised, an abstract of the paper on

Electric Street Tramways.

BY ROBERT HAMMOND, M.I.E.E.

On the occasion of last year's annual meeting of this association, at West Bromwich, an inspection was made of the South Staffordshire Electric Tramways, serving about eight miles of the immediate vicinity. The writer had the pleasure of accompanying the members on that visit, and is now glad to have the opportunity of complying with the request then made that he should read at this meeting a paper on "Electric Street Tramways," in order to create discussion upon a subject rapidly growing in importance. At the outset the writer would like to make it clear that he approaches the problem absolutely without personal bias. He has no particular system to push and no special form of apparatus to advocate. His main desire is to lay before the association the arguments in favour of the adoption of electric tramways in this country, especially in connection with municipal electricity supply works. By the courtesy of Messrs. Siemens and Halske, of Vienna, he last year was enabled to make a complete inspection of the electric tramways at Budapest. Over street crossings a speed of only 3·7 miles is allowed, but on straight runs a speed of nine miles is often reached, and on the branch to Steinbruch a speed of 15 miles. On this portion the wires are, however, carried overhead. In the heart of the city passengers frequently ride for ridiculously short distances, the minimum fare being six kreuzers, less than 1¼d. (1·2d.). The track is so solidly laid that the cars glide smoothly along without jolting or rattling. Sharp stopping and starting is admirably effected, there being an entire absence of jibbing. No electrical skill is required to drive the cars, the drivers being very low-waged men. There are 56 cars running on ordinary days and 72 on Sundays. As many as 60,000 people have been carried in one day, and last year the total number of passengers was upwards of 13,000,000. The gross revenue last year amounted to £81,330, the working expenses £48,878, and the net earnings £32,452. It must be acknowledged, however, that conditions at Budapest are extremely favourable. The bulk of the streets are flat, while a very gentle slope to the river assists the drainage of the conduits. There is only one steep gradient in the whole run. Though Budapest is important as affording an almost unique example of the conduit system, there are many other cities in Europe where electric tramways or railways are in operation. I give in Table I. the complete list.

It will be noticed that there are 47 lines in operation, the total length being 194½ miles, and the horse-power employed 14,579 i.h.p.

It is in the United States, however, that electric traction has reached the greatest development, as will be seen by the latest published data to the end of 1893, to which, however, considerable additions would doubtless have to be made in order to bring it completely up to date:

	Mileage of line.	Cars.
Horse tramways	3,486	15,680
Electric ,,	7,671	17,974
Cable ,,	676	4,867
Steam ,,	536	657
Total	12,369	39,178

It is interesting to consider the reasons which have led to the great extension of electric traction, and to the almost universal opinion that horse traction must eventually disappear from all main routes of tramways. One of the past-presidents of your association, Mr. G. Laws, the city engineer of Newcastle-on-Tyne, has, within the past few weeks, presented a most able report to his Tramways Committee on the best system of tramways suitable for Newcastle (*vide* the *Electrical Engineer* of June 8, 1894).

One of the most pressing problems encountered by members of corporations, and especially by borough engineers, is that

connected with the overcrowding of ever-increasing urban populations; and one of the easiest, and at the same time soundest, solutions of the problem is the provision of cheap and expeditious transit, by which the spreading out of the population is facilitated, and pure air and more wholesome surroundings are placed within the reach of the great bulk of the ratepayers.

We have, then, to consider how this cheap, quick transit can be best obtained. To quote from Mr. Laws's report: "It seems unnecessary to further consider horse traction at all. It has done fairly well in the past, and has served its purpose and become obsolete as not meeting the public wants. The town, in fact, has outgrown it, and wants something more modern and offering greater facilities in speed, accommodation, and cheapness." The choice, indeed, lies between electric cable, steam, gas, and oil traction. Each one of these methods is of sufficient importance to form the subject of a separate discussion, and for the purpose of keeping the present paper within the prescribed limits, attention is limited to electric traction.

The first requisite in electric traction is a "central station," as it was first named, though more recent practice dictates the term "electricity supply work," or even "electricity works," like gasworks—or, more ambiguously, "power-house." Granted, then, the existence of electricity works—owned, it is to be presumed, by the local authority—the next point to be considered is how the electrical energy produced there can be made to do traction work—one, three, or, if need be, five miles or more away.

Considering that a tramcar must by its very nature run on a pair of rails, it would appear to be a very simple thing to connect one rail to the positive pole of the stationary dynamo and the other to the negative pole, so that the one rail should form the outward path for the electrical energy and the other the homeward path. Such was the plan adopted by Mr. Magnus Volk in his little pioneer electric railway at Brighton. The children playing on the beach soon learnt by sundry practical demonstrations *in corpore vili* to avoid those rails, though the more mischievous took their revenge by surreptitiously placing conductors across them, often thereby affording the electrical energy an easier path back to the stationary dynamo than that provided by Mr. Volk through the motor on the car, so bringing the same to a standstill. The E.M.F., or difference of pressure between the rails, was not enough to do bodily harm, it being possible to keep it low on account of the shortness of the length of line. The first electric railway constructed by Messrs. Siemens and Halske, at Lichterfeld, was on this system, but the track is raised about 6in. above the level of the public road in order to prevent other vehicles using it. It is evident, however, that open rails capable of administering shocks, however far removed from dangerous, could not be tolerated in the public streets, and attention was early given to other means of conveying the

Digitized by Google

electrical energy to the moving car. The main systems may be divided into (I.) accumulator ; (II.) overhead ; (III.) conduit.

I. The Accumulator System.

In this system the stationary dynamo is used to "charge" secondary batteries or accumulators. These are packed in batches under the seats of the car, and when it speeds on its course all difficulties with regard to the method of conveying the electrical energy to the motors vanishes, the moving power being, of course, carried on the car itself. Here would appear to be a model system of electric traction, but, unfortunately, the drawbacks to the present methods of "storing" have hitherto proved a complete bar to its extension. The constant chemical changes taking place—some essential, others unavoidable—eventually rot away the plates of the best batteries. It will be seen that "storage" is altogether a very complicated process. Again, the plates secure the longest life by a slow and regular rate of discharge, but the conditions of tramway working involve exactly the opposite, in consequence of the constant stoppages and the varying gradients. Before dealing specially with the question of weight it will be well to dispose of the question of deterioration. Not only is this accelerated by the rapid variation of the output, but it is also increased by irregularities in the track causing jolting. When the storage system was abandoned in Brussels, it was stated that 200 days was the length of life of the positive plates. Reports from other places give the life of batteries at less than a year. It is true that a longer life is claimed by some makers, but it may be stated with certainty that the cost of maintenance of accumulators, running up sometimes to 100 per cent. per annum, is, with the cells at present in use, except under exceptional treatment in the hands of experts, never below 50 per cent. per annum. Returning to the question of weight, taking 72 cells as a usual number, the total weight works out 3,600lb., or rather more than 1½ tons. The cars must, of course, be built on stronger lines to carry the extra weight. In America a standard 16ft. car, with its two 15-h.p. motors, weighs about five tons, and in addition of the accumulators brings it up to about seven tons. In some recent statistics on the subject published by Mr. Epstein*, 10 tons is given as the weight of the accumulator car, as against eight tons, the weight of an ordinary car, including, in both cases, 40 passengers. The heavier cars pound the track in a way to cause serious deterioration. The heavier weight has always to be conveyed, "hail, rain, or shine." Mr. Epstein, a strong advocate of accumulator traction, gives in the article above mentioned the following table :

Table II.—Estimated Cost of Working—Accumulators.
Cars for 40 passengers.

	Pence per car mile. L.	H.	A.
1. Running expenses—			
(*a*) Fuel	·20	·60	·40
(*b*) Oil, waste, and sundries	·03	·08	·05
(*c*) Brushes on motors and lubrication	·10	·30	·20
(*d*) Wages at charging station	·50	1·00	·75
(*e*) Drivers' wages	·50	1·00	·75
	1·33	2·98	2·15
2. Maintenance of roads	·50	1·00	·75
3. Repairs of cars	·25	·75	·50
4. Traffic expenses—			
Wages of inspectors, cashiers, timekeepers, conductors, tickets, and miscellaneous	1·00	2·00	1·50
5. General charges—

L. Lowest. H. Highest. A. Average.

The only two accumulator lines in Europe are the Saint-Denis line in Paris, and that belonging to the Birmingham Central. The cars on the Saint-Denis line weigh 12 tons, including passengers. A recent return gives the cost of working per kilometre run at 53 centimes, as against 56 centimes for horse traction. This is equivalent to slightly over 8d. per car mile. With regard to the Birmingham Central line, Mr. Broekman, the engineer, as the result of daily tests, gives 3·928d. as the cost of traction per car mile run. The total costs, as gathered from the last report, were 16·55d., being an increase of 1·16d. upon that of the previous year. There would appear to be a large margin for economies in management. The net loss on the year's running was £98, as compared with £1,600 in the previous year. On a recent inspection of the line the writer found a most satisfactory, smooth, trustworthy, and apparently very popular 10 minutes' service. With regard to capital outlay, the advantage would be on the side of the accumulator system in the case of a long run with a few cars, though on a line with a large number of cars this advantage would be lost. Capital outlay is, of course, largely affected by local conditions, but £7,000 per mile for 10 minutes' service may be taken as a guide of the cost of the accumulator system. Finally, with regard to cost of running, the results of actual work in the United States tend to show that the accumulator system requires an expenditure of 1·5 horse-power hour per car mile, as against 1 h.p. of of the overhead system. This is, of course, due to the extra dead-weight carried. If this dead-weight could be reduced without impairing the all-round efficiency of the accumulators, their use for traction would be greatly facilitated. Before the paper is closed, attention will be drawn to means by which possibly they could be advantageously used, in spite of all their drawbacks.

* Including City and South London Underground and Liverpool Overhead.

Summary.

Overhead wires	36
Conduit	2
Accumulators	2
Third rail	7
Total number of electric tramways and railways in Europe	47

It will be seen that by far the largest number of street tramways in Europe are worked by means of overhead wires, and in the States the whole of the 8,000 miles in operation are so worked. The South Staffordshire Electric Tramways, inspected by the members of the association last year, as well as those at Roundhay Park, Leeds, are on this system. The latter line is erected exactly on the American plan. On the South Staffordshire line the use of the span-wire system is avoided. Mr. Alfred Dickinson, A.M.I.C.E., the engineer of the line, designed a system by which the "trolley wire" and feeders are carried on one side of the road, contact being made with a "fishing-rod" arrangement.

Mr. Dickinson, the engineer of the South Staffordshire line, states last year's working costs to be 4·6d. per car mile run. Mr. Graff Baker, who superintended the laying down of the Leeds line, has entered into a contract to equip a similar line in Coventry. It is evident that an overhead system affords the cheapest method of conveying the electrical energy to the car. Before the Electric Powers (Protective Clauses) Committee evidence was given that in Leeds the cost of running the electric line was 5½d. per car mile as compared with 7·77d., the cost of steam and horse traction in the same city, and before the Electric and Cable Railways Committee Mr. Preece stated that 6d. per car mile was the average cost of running in the States. There the success of the overhead system has indeed been very great. Messrs. Crosby and Bell,* in reference to the American electric trams, says : "Experience thus far shows that the substitution of electricity for horses is followed by an increase in gross receipts ranging from 25 to 300 per cent. over the original receipts. Even when the service with horses has been good, considerable increase (rarely less than 30 per cent.) is marked. No better evidence could be had of the desirability of the electric railway. The expense per car mile will generally prove to be less than by horses. We say generally because in a city where horses and forage are exceedingly cheap, while coal and mechanical skill are unusually high, it might be impossible to secure the economy usually counted upon. As an illustration of the difference, exemplified on a large scale, we subjoin a statement (Table III.) made by the West End Railway Company of Boston, showing the greater economy per car mile of electric traction. It is to be noted in this case that the figures for horses represent the result of years of effort toward the best attainable practice, while for electric traction the figures cover contract prices for repairs made very early in the history of the business, and consequently at a higher price than would now be made. Moreover, the practice generally being new, it remains for time to develop those small economies which show a system at its best. For both horses and electricity these

Car repairs per mile	1·39	0·93	1·57	0·03
Damages per mile	0·75	0·78	0·23	0·10
Conductors and drivers per mile	7·33	8·28	6·85	8·10
Other expenses per mile	4·63	4·70	5·C0	4·81
Total expenses per mile	21·75	25·56	20·69	23·37
Earnings per mile run	34·05	31·77	37·45	35·80
Net earned per mile	12·30	6·22	16·76	12·43

figures of cost are high as compared with the rates attainable elsewhere. Coal, forage, and labour are in Boston well above the average for the entire country." It is a question whether the prejudice which exists in England against overhead wires will be overcome by the facilities which the system offers to cheap and rapid transit. Even if it be deemed that the system is not suitable for a crowded town or city, it may be acknowledged as quite permissible in the suburbs. The opinion of the members of the association would be of great value on this point.

Before closing the remarks under this head, attention must be drawn to the extremely good results given by lines employing a "third rail" as the conductor. The earliest example of this method is the line which was opened for traffic over 10 years ago, and which is still doing excellent work between Portrush and Bushmills, in the North of Ireland, a distance of six miles. The "third rail," which brings the electrical energy to the motor, consists of T-iron weighing 19lb. per yard. It is carried on creosoted wooden posts, 10ft. apart and 22in. from the inside rail, and 17in. above ground. Limit of speed 10 miles an hour. Following close upon this line in point of time was another "third-rail" line—namely, that constructed by Messrs. Mather and Platt between Bessbrook and Newry. In this line the conductor consists of inverted channel steel, laid midway between the rails. It is worked by water power, and the costs per tram mile were, according to the last data published, as low as 3·94d. The City and South London costs (third rail) work out at 7d. per 30-ton train mile: but this is deemed high, and 10d. is taken as the estimate of cost of the 180-ton trains on the proposed Finsbury Park electric line.

III. CONDUIT SYSTEM.

By means of this system the objectionable overhead wires are dispensed with, and the drawbacks to the use of accumulators avoided. It is, however, significant that there are, beyond the two experimental lines mentioned by Mr. Preece, no conduit systems now in operation in the United States, while there are only two in Europe. At the opening of the paper a description was given of the working of the Budapest tramways, and attention drawn to the excellent results obtained there. The car mile cost of running in 1893 amounted to 5·14d., taking the florin at equal to 20 pence. As already pointed out, large profits are being made annually, and it has recently been decided to extend the system throughout the whole city, and to entirely abolish horse traction. The Metropolitan Traction Company have just contracted with Messrs. Siemens and Halske to construct a similar line in New York. The only example of the conduit system in this country is that at Blackpool, which was laid down in 1883 by Mr. Holroyd Smith. The conduit here is only 12in. deep, as against 27½in. at Budapest, and the slot ½in. wide at the top, as against 1 1/8in. As the line runs the whole length of the esplanade, the conduit is frequently flooded by the tide twice a day, the water depositing therein shingle, stones, and sand. The line has, however, during the past few months been thoroughly overhauled, and the electric cars have been restarted most successfully this week. So satisfied is the Blackpool Corporation with the conduit system that large extensions are projected. In defence of that system they have, within the past few days, successfully sustained their case before the Board of Trade against the opposition of a tramway company fringing their borders. The cost of running is returned for 1893 at 5d. per car mile, though older statistics placed it much higher. Indeed, it is claimed that if the bad condition of the road had not prevented continuous running, the 1893 cost would probably have been as low as 3·5d. per car mile. In addition to the lines in work at Budapest and Blackpool, there are other "conduit systems" which have been designed, but as they are not yet in actual work, and only differ in technical details, they need not be here described. The writer wishes to state his conviction that there are many towns in this country where a properly-designed and solidly-constructed conduit system would prove a great success.

BEST METHODS OF "GENERATING" THE ELECTRICAL ENERGY.

Having now described the various systems of electric traction, consideration may profitably be given to the most economical method of "generating" the electrical energy for running them. The writer is convinced that low costs can best be attained by a combination of electric traction with electric lighting. In connection with the running of electricity supply works for electric lighting, he has had during the past 10 years to carefully consider the costs of production of electrical energy. The popular idea is that by far the greatest cost is that of coal, and that preference should be given to plant providing for low coal consumption, with regard first to steadiness of running, easy manipulation, cheap maintenance, etc. The actual position held by coal may be seen by the following statement:

TABLE IV.—Average Cost of Producing Electrical Energy in 24 Electricity Works in the United Kingdom in 1893, excluding depreciation.

		Pence per 1,000 (watt-hours).	Percentage.
Coal	£48,503	1·02	28·97
Oil, waste, water, stores	11,388	·24	6·80
Salaries of engineers and works wages	41,450	·87	24·77
Repairs and maintenance	23,441	·49	14·00
Rents, rates, and taxes	8,762	·18	5·21
Management	33,915	·71	20·25
11,411,176 units	£167,459	3·51	100%

An examination of the above percentages show that the value of the raw materials used in an electricity supply works, practically devoted exclusively to lighting, only amounts to 35·77 per cent. of the total annual costs, and it is confidently believed that this percentage will be considerably decreased. It is manifest, therefore, that an increase of the duration of the daily load, not necessitating additional plant or additional labour, would only affect the coal, etc., bill. On these lines it will be seen that, supposing the load were doubled, the resulting cost would be:

TABLE V.	Cost of production of electrical energy. 1 unit.	2 units.
Coal, oil, waste, stores, water, and sundries	1·26d.	2·52d.
Other charges	2·25d.	2·25d.
	3·51d.	4·77d.
Or per unit		2·38d.

If the load were similarly multiplied, say, four times, with, perhaps, an increase of 20 per cent. on the other charges, the result would be:

TABLE VI.	Cost of production of electrical energy. 1 unit.	4 units.
Coal, oil, waste, stores, water, and sundries	1·26d.	5·04d.
Other charges	2·25d.	2·70d.
	3·51d.	7·74d.
Or per unit		1·94d.

As a matter of fact the coal bill would not be augmented in exact proportion to the load, because in electric lighting works the time of "small load" presses very unremuneratively on the coal consumption; indeed, it might be fairer to assume that the quadrupling of the load would be effected at the expense of only trebling the coal bill, etc. On the other hand, it may be urged that four times the load, though spread over the usual working hours of the "central station," could not be coped with at an increase of only 20 per cent. upon the "other charges." The writer is, however, content to leave the estimate as it stands,

Digitized by Google

in order to illustrate the fact that a lengthening of the hours of active use of the electricity works plant would lead to considerably lower costs all round. The combination, indeed, of electric traction and electric lighting would appear to be a most beneficial one. At the opening of the day, when the trams start operation, there is no load upon the electricity works, and this absence of load practically continues till sunset. Here, then, is a most convenient use for plant otherwise lying idle. In the case of electricity works specially confined to traction, the whole of the standing charges are, of course, debited to the cost of the car mile run, whereas, if worked in connection with electric lighting, only a portion of those charges would be debited. It must, however, be borne in mind that at one period of each evening the electric lighting load and the tram load would clash, and this has hitherto been considered a bar to the combination of the two works. It is fully admitted by the writer that the overlapping of the loads is a matter of great moment, and the means by which it can be coped with will have to be carefully thought out. He is, however, convinced that an economical arrangement can be arrived at. It will be seen at once that the accumulator system is that which lends itself most readily to the combined plan. The duration of the top load in electric lighting works varies according to different localities, but it frequently lasts for less than one hour. Up till the moment of reaching it there is a margin of capacity in the plant for doing the work of charging the batteries, and from the moment the load begins to fall off the margin of capacity is released, so that in the case of the accumulator system it would be only necessary to cease storing for about one hour; and, on the other hand, extra storing would be effected during the hours of the night when the electric lighting load was practically nil, and the trams were not in operation. In the case of systems of direct supply, it might still be possible to tide over the period of maximum electric lighting load by secondary batteries fixed in the station, which, charged during the day, could be used at the critical period to give out the electrical energy necessary to feed the motors on the cars. As soon as the electric lighting load began to fall off, the dynamos thereby released could be put on to the traction work. It would, of course, never be desirable for the lighting and the traction work to be coupled together from the same dynamo, as the heavy variations of the traction load would cause unpleasant fluctuations in the light. There is a third plan which the writer has lately been considering, and which might, indeed, prove the most economical method of dealing with the overlapping difficulty—viz., the horsing of the tramcars during the time of the top lighting load. In conversation with a leading provincial jobmaster, the writer finds that in many cities horses are jobbed out to do purely light day work, and that it would be a boon to the jobmaster to be offered employment to which they could be put during the evening. As doubtless the members of the association have the control of the horses belonging to their respective local authorities, it will be useful to gather their opinion upon this point. By whatever means, however, the overlapping load may be coped with, the writer urges that it by no means presents an insuperable difficulty, and even though, comparatively speaking, it may not be dealt with economically, the advantages of the combination of traction and lighting in one works completely outweigh the disadvantages connected with the less economical running of the trams, for a short time daily.

As mentioned last week, the discussion on the papers presented by Mr. Shoolbred and Mr. Hammond was taken together. It was very brief, and was as follows:

Mr. Crompton said there was a mistake of 50 per cent. in the working cost of the last mentioned in the list of companies working on the low-pressure system. This was of great importance in view of the great battle which had raged as to the best system of electric lighting. One body of electricians held one system to be correct, and the other held very different views. The result had been very puzzling to the various committees who had investigated the electric lighting of towns. On that very important point Mr. Shoolbred's paper was highly instructive. He showed results which redounded greatly to the credit of those in charge of the Bradford installation, and he must say that Mr. Shoolbred and his engineer, Mr. Baynes, were to be congratulated on the results of their four years' extremely hard work. There was no doubt Mr. Shoolbred was to be congratulated on having been firm enough to get his committee to adopt the system which had been adopted. The committee had been strongly attacked for not having adopted the high-pressure alternating system. The right-hand column showed if they had done so their working costs would have been considerably higher, and instead of being a financial success the works would not have been a success. He knew what he was saying was of a highly controversial nature, and might be contradicted by those who followed him, but when he told them that Lord Kelvin, the late Dr. Werner von Siemens, Prof. Hefner von Alteneck, of Berlin, and Prof. Kennedy, who probably advised more towns than anyone else in England, were of the same opinion on the matter, they would see he was one of a very strong army. The whole point was this: towns that they were proposing to supply electrical energy to varied very much in their requirements. Most provincial towns consisted of a condensed business quarter and a suburb of villa residences in which the business men engaged in the town during the day lived in the evening; and the difficult problem was how to put down works to supply these two classes of buildings in the most satisfactory manner, and at the cheapest possible cost. It was extremely difficult for corporation committees to choose between those who held these divergent views. Those who advocated the high-pressure system were able to show that their plant would cost less money; those who thought with himself that the comparative safety and moderate pressure adopted at Bradford were the best, were able to show that though the capital to be raised in the first instance was higher, the working costs were so much less that even with the added cost of capital it did not reach the high figure it reached where the high-pressure system had been adopted. Personally, he was in a peculiar position. He advised three of the largest companies in London, and those works were on the low-pressure system, and he held three-fourths of the capital of a high-pressure alternating system providing the electric light to a provincial town, and his pocket had suffered thereby. He had had every opportunity of making it as economical as possible—he was alluding to Chelmsford—and he was just making it turn the corner; whereas with other towns this turning of the corner had taken place some years ago. Of the municipal corporations who had taken up electric lighting, Bradford was the oldest, and was a success. Hull was also very well satisfied with the results of its undertaking. The four low-pressure companies in London were paying an average of 5 per cent. on their capital. If they turned to the other side, there were only two companies—those at Newcastle—which were paying any interest on their capital when invested in high-pressure plant. The reason was not far to seek. At Newcastle coal was purchased at 3s. 2d. to 5s. 6d., and they had consequently been able to show exceptionally low working costs in their exceptional position. The advocates of the high-pressure system invariably pointed to those two companies to prove the success of the system, and it was high time this matter should be shown up. In that room he had already read a long paper, which was subjected for two nights to the discussion of engineering experts, and he was then able to show that at Newcastle the absolute working costs as regards fuel and labour and all the items which went to make up the real costs of electricity as apart from management and sinking fund, were 2½ to three times as great at Newcastle as when they were compared with equal prices of coal to the cost of working the low-pressure system in London. His remarks on Mr. Shoolbred's paper would not altogether suit Mr. Hammond; but as regard Mr. Hammond's own paper it was one of very great interest, and its only fault was that he had not made his case strong enough. He had put before them a very moderate case as to municipalities taking up the driving of trams by electricity.

Mr. R. Hammond said he was very much obliged for the opportunity of a six minutes' speech, as a set off against his paper being crowded out. He was hardly able in that six minutes to follow Mr. Crompton in his discussion of Mr. Shoolbred's paper. He would only say it was, perhaps, to be regretted that from the point of view of the association that Mr. Crompton did not deal with the subject of municipal electricity works generally rather than laying before them a plea for any particular system. With regard to electric trams, he was very pleased to hear from so close an observer as Mr. Crompton that he thought he (Mr. Hammond) had put his case too weakly, or at all events he had not put it as strong as he might have put it. The great argument he wanted to drive home in his paper was this—that in electricity supply works there were perforce a great many idle hours. From six o'clock in the morning to sunset there was, roughly speaking, no load whatever upon an electricity works. Of course, he knew that in some works a certain amount of accumulating was done during the day, and for the details and explanation of his short remarks he must refer them to his paper. Let them take it on the broad principle that lighting was not required during the day, and from half-past five to six o'clock in the morning there was a capacity in the electricity works which might very well be utilised for tramways. He need hardly, before gentlemen so well acquainted with the principles of cost and standing charges, draw their attention to the fact of how markedly costs were decreased by an increase of output. But he would like to say this, that this was especially so in the case of those works that obtained an increase of output, not by doubling the work at one particular end of the day, but by doubling the hours' duration of work. If in any electricity works—Bradford, for instance—they were in the course of the next 12 months to double the number of lights that were now attached to the station, and fed from it, then necessarily there would be a double plant and a double cost; but if they glanced at the diagrams which Mr. Shoolbred had so ably prepared, and which set forth the position so exactly, they would see it was only in a certain portion of the evening that the top load was reached and that it rapidly fell away. Therefore any broadening out of the groove would simply lead to an increase in the use of raw material. All the standing charges would be the same, roughly, though in his paper he had provided for a further 20 per cent. beyond the coal bill. This appeared to offer a solution to the difficulty which electrical engineers were suffering under of reducing the cost of electrical energy. He had taken the 24 companies which made returns. He had not taken particular works, but those whose Board of Trade returns were available. He admitted there was a difficulty which was manifest to all, and that was the overlapping of the load. The reply was, it was all very well to begin at six o'clock in the morning, but what were they going to do when the double load came on at night. He quite believed the difficulty of the overlapping of the load could be coped with electrically, but

Digitized by Google

rather than run the two he would bring out horses for a couple of hours and horse the trams. He was told by a jobmaster that those horses which went in at three or four o'clock in the afternoon could be used for the critical period. What he wished to establish was that there was idle plant which could be used in the direction of traction, with the result of greatly reducing the costs all round.

LEGAL INTELLIGENCE.

DICKINSON v. SCOTT.

This action, in which Mr. Ronald A. Scott, M.I.E.E., etc., was sued in the County Court of Durham, at Stockton-on-Tees, for hire of a building, warehousing, and work in connection with the exhibition of his electric advertising apparatus, came recently before two judges of the High Court sitting at a Divisional Court of Appeal, on a motion by Mr. Scott to set aside the judgment of the Court below.

Mr. C. Arnold White appeared for the appellant, and Mr. Jarburgh Anderson represented the respondent.

This action had turned on the question whether a claim by a certain Mr. Folkard, who was a general agent for sale of electrical apparatus for Mr. Scott in the North of England, was in consequence and impliedly an agent for the purpose of pledging his credit in connection with the exhibition in question, which was held at Middlesbrough, preliminary to negotiations for the acquisition by Mr. Folkard and his friends of a sole license for use in the northern counties for a certain sum. His Honour Judge Turner held that Mr. Folkard had this authority, and in consequence Mr. Scott must pay for rent of the building and the work done by the plaintiff, Mr. Dickinson, and his workmen, but not for warehousing the apparatus after the exhibition. Mr. Scott had counterclaimed for damage sustained by the detention of the apparatus. The counterclaim was disallowed, and the defendant was to pay the whole claim (except the portion for warehousing) and costs. He thereupon appealed to set aside this judgment, and for a new trial upon the counterclaim on the ground that the judgment was wrong in law.

The motion was heard before Mr. Justice Cave and Mr. Justice Collins in June last, and, after considerable argument by the learned counsel, the hearing was adjourned for a week on their lordships' suggestion with a view to settlement.

We understand that this has now been arranged to the satisfaction of Mr. Ronald Scott upon the terms that he should be repaid all the costs and the whole of the money paid over upon judgment in Mr. Dickinson's favour on the claim, and, in addition, a substantial sum to cover costs and damages upon the appeal.

COMPANIES' MEETINGS.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

An extraordinary general meeting was held on Tuesday to approve of a provisional agreement for the sale of the Swan Company's undertaking to the Company.

Mr. James Staats Forbes, who presided, said: We have called this meeting, not because there was any legal necessity to do so, for this is a matter which was in the competence of the Board to commit you to without confirmation. That, however, is not the way in which we do business in this Company; we like the shareholders to come in and confirm what we do. We made it a condition of this bargain, and of the vote we took on behalf of the Swan people, that the agreement was still open to objection if the Edison and Swan Company, as a separate company, did not confirm it at this meeting; therefore, we have called you together. The discussion which took place at the previous meeting had, among other advantages, that of giving me an opportunity of stating what the position is. The Edison and Swan, in which we ourselves are considerable partners, has such a common interest with the Swan Company that we thought it prudent to acquire that portion of its business which was not absorbed in the original amalgamation of the British patents. We are now the subjects of active competition, and this being so, we came to the conclusion that it was very desirable to join our forces, so as to present a united front to the enemy, not only in Great Britain, but also on the Continent, and for that residuum the Swan Company has agreed to accept £100,000 of debentures. The question we have to determine to-day is whether the Edison and Swan Company is willing to give that for it. I do not know whether anybody will be prepared to express disapprobation of it, or to use arguments which will induce us to reconsider our decision. If they are so prepared, we are at their service. I now beg to move the following resolution: "That the provisional agreement, dated June 5, 1894, submitted to this meeting, and expressed to be made between the Swan United Electric Light Company, Limited, and this Company, for a sale of the Swan Company's undertaking to this Company for debenture stock of this Company, be, and the same is hereby, approved."

Major Flood-Page, in seconding the resolution, said that every single director and every official connected with the management of this organisation was in accord in thinking that if they were to make a success of that undertaking they must have this fusion.

The resolution was then put and carried without discussion.

SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

An extraordinary general meeting was held on Tuesday at Cannon-street Hotel, E.C., under the presidency of Mr. James Staats Forbes (the chairman).

The **Chairman**, in the course of his remarks, said: I assume that everybody is conversant with the resolution now to be submitted, and therefore my business is very simple. The whole matter was fully discussed at the former meeting, and it was thought desirable, in the interests of all concerned, that the agreement should be approved. I will therefore content myself by proposing the confirmation of the following resolution: "That the Swan United Electric Light Company, Limited, be wound up voluntarily, and that Henry Charles Gover, of 100, Victoria-street, in the city of Westminster, be, and he is hereby, appointed liquidator for the purpose of such winding up, and that the liquidator be, and he is hereby, authorised to carry into effect, upon the terms of a provisional agreement between the two companies dated June 5 (subject to any modification), a sale of the Company's undertaking to the Edison and Swan United Electric Light Company, Limited, for debenture stock of that company, to be distributed among the members of this Company."

Major Flood-Page seconded the resolution, which, after some discussion, was unanimously adopted.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY.

The first ordinary or statutory meeting of the shareholders of this Company was held on Wednesday at Winchester House, Old Broad-street, in compliance with the Companies' Act, 1867, Mr. William Addison occupying the chair.

The **Chairman** said that the reconstruction arrangements had proceeded satisfactorily. The new Company was registered in the afternoon of the day on which the resolution was passed by the old company, and the business had since been conducted without any drawback. There was every reason to believe that the shares were well and firmly held, as there had been but few transfers. The Company's business was showing fair progress, the reports from the various agencies and the affiliated companies being satisfactory. With regard to India, the volume of business showed a satisfactory increase, but the depreciation of silver necessarily affected them. The new company having only been formed on March 12, they could not at that meeting bring forward any report or balance-sheet, but they would do so at the earliest opportunity next year, which would probably be in April. As there was no special resolution to put before the meeting, he would be happy to answer any question.

No questions being asked, the Chairman declared the meeting at an end.

BUSINESS NOTES.

Glasgow.—Electrical plant for the illumination of the tramway depôt is being laid down at the depôt.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 1st inst. amounted to £894.

Direct Spanish Telegraph Company.—For the month of June the receipts were £1,617, as against £1,730 for the corresponding period of last year.

Cuba Submarine Telegraph Company.—For the month of June the receipts were £117 more than for the corresponding period of last year.

Eastern Extension Telegraph Company.—For the month of June the receipts show a decrease of £1,199 as compared with the corresponding period of last year.

West India and Panama Telegraph Company.—The receipts for the two weeks ended June 30 were £16 less than for the corresponding period of last year.

Tenders for Buildings.—The London County Council invite tenders for the construction of the buildings in connection with the electric lighting of the embankment.

Lecturer Required.—An assistant lecturer in mathematics and physics is required for the Battersea Polytechnic Institute. Particulars may be obtained of the secretary.

Brasyer v. Harness.—Colonel Brasyer is endeavouring to secure the return of money from Mr. Harness and the "Medical Battery Company," and he also claims damages for negligence.

Bolton.—The electric lighting works, which have cost something like £40,000, along with plant, are approaching completion, and in a few weeks the Corporation expect to be in a position to supply this illuminant.

Newcastle.—The Finance Committee of the Town Council have reported on the proposed alterations in the Town Hall. The estimated cost of installing the electric light is £470. The report stands over for consideration.

Windermere and District Electricity Supply Company, Limited.—This Company has been registered with a capital of £50,000, in £5 shares, to carry on business as electrical engineers, electricians, engineers and contractors, etc.

Wolverhampton.—The directors of Messrs. Thos. Parker, Limited, have accepted the contract of Mr. H. Lovatt, builder, etc., Wolverhampton, for the erection of their new electrical engineering works in the Wednesfield-road.

Digitized by Google

Eastern Telegraph Company.—The directors recommend, after placing £110,000 to the reserve fund, a further dividend of 2s. 6d. per share and a bonus of 3s. per share, making a total distribution of 6½ per cent. for the year ended March 31 last.

Newport (Mon.).—The first lengths of a new line of tramway, owned by the Corporation, have been laid. According to a Welsh paper, it is hoped that in no long period electric traction will be adopted, and that the cars will be lighted electrically.

Mason's Stair Treads.—The Safety Tread Syndicate, Limited, of 15, Barbican, E.C., inform us that Mason's unwearable non-slipping stair treads have been introduced as the covering for the stairs in the towers of the new Tower Bridge opened on Saturday.

Electric Novelty Syndicate, Limited.—This Company has been registered with a capital of £4,500 in £1 shares to carry into effect an agreement between R. Myers and this Company for the acquisition of certain patents relating to improvements in electrical toys.

Business Notice.—We are requested to state that Messrs. Habgood and Smith, of Queen Victoria-street, and Great Missenden, are in no way connected with the British Volta Electric Glow Lamp Company, of 49, Queen Victoria-street and Great Missenden, Bucks.

St. James's and Pall Mall Electric Light Company.—The directors have declared an interim dividend on the first preference shares at the rate of 7 per cent. per annum, and on the ordinary shares at the rate of 4 per cent. per annum for the half-year ended June 30.

St. Pancras.—The Vestry have sanctioned the outlay required for wiring the buildings under the control of the Board of Guardians and the Committee of the Baths and Washhouses. It is stated that it will be at least 12 months before the scheme can be carried out.

Edinburgh.—The Cleaning and Lighting Committee of Edinburgh Town Council on Monday agreed to recommend that George-street, St Andrew-square, Charlotte-square, and streets leading from these thoroughfares into Princes-street, should be lighted by electricity.

Coventry.—The Electric Light Committee of the City Council report that 106 applications have been received for the post of clerk of works at the new buildings, and that Messrs. A. Davies (Coventry) and J. B. Crawford (London) are to meet them with a view to final selection.

Fraser and Fraser, Limited. — This Company has been registered with a capital of £30,000 in £1 shares to acquire the business of engineers and boilermakers now carried on by Fraser and Fraser at the Railway Works, Bromley-by-Bow, and Monument-chambers, King William-street, E.C.

Dover.—At a meeting of the Town Council, Councillor Clark said that observations had been made because the town men were employed in laying down the mains. He wished it to go to the public that this was done by agreement, and the company were paying the Council for the work done by them.

Lancashire Boiler Required.—The Hereford Gas Committee invite tenders by the 21st inst. for the construction and fixing of a Lancashire steam-boiler. Specification may be seen and the drawings and site inspected on application to Mr. William Parlby, gas engineer and manager. Gasworks, Hereford.

Tenders for West Ham.—As mentioned in our last issue, tenders are invited for the electric lighting at the Public Hall and Free Library, Barking-road, Canning Town, E., for the West Ham Town Council. Tenders are to be sent to Mr. Fred. E. Hilleary, town clerk, Town Hall, West Ham, by 10th inst.

Mill-Lighting.—Messrs. Bennett and Druce, of 30, Winckley-square, Preston, have secured an order for a complete plant consisting of engine, dynamo, and fittings for a mill situated in the North-West Provinces of India. The engine is by Messrs. Marshall, Sons, and Co., Limited, of Gainsborough.

Extension of Patents.—The Electric Construction Company, Limited, and the Electric Power Storage Company, Limited, who are exclusive licensees under Camille Faure's patent for improvements in batteries, intend to present a petition praying that the said letters patent may be extended for a further term.

Elmore's German and Austro-Hungarian Metal Company, Limited.—It is announced that, owing to continued ill-health, the chairman (Mr. Rock) has been compelled to resign his seat on the Board of this Company, and that Mr. John Heal, of the firm of Bloor and Heal, of Snow-hill, E.C., has been appointed a director of the Company.

City and South London Railway.—The receipts of the Company for the week ended July 1 were £1,020, against £811 for the corresponding week of 1893, or an increase of £209. The total receipts for the half-year ended July 1 were £23,636, as compared with £22,610 in the corresponding period of 1893, or an increase of £1,026.

Removal.—Messrs. Winfields, Limited, of Birmingham, are removing their London sample-room to 30, Snow-hill, E.C. The London business is under the management of Mr. Seymour Croneen, and arrangements are being made for the display in the new showroom of a fresh selection of samples, including the latest designs in gas and electric light fittings.

Birmingham Trams.—In moving the adoption of the report of the Public Works Committee of the Town Council on Tuesday, Mr. Smith said he thought the committee would have the approval of the Council in refusing the tramway company permission to adopt the overhead wires on the Bristol-road route. They were very unsightly, and would disfigure the road.

Engineer Wanted.—The Corporation of Wolverhampton invite applications for the appointment of working foreman engineer for the electric works, at a salary commencing at £2 per week. Applications must be made on forms to be obtained from Mr. F. Harman Lewis, borough electrical engineer, Town Hall, Wolverhampton. The forms must be returned by 14th inst.

Tenders for Wolverhampton.—As stated in our last issue, the Lighting Committee of the Corporation of Wolverhampton invites tenders for the supply of electric fittings suitable for the Town Hall, Art Gallery, School of Art, Free Library, and Market Hall, and for the electric wiring and erection of selected fittings. Further information is given in our advertisement columns.

Darwen.—The architect of the new technical school has been instructed to prepare plans and estimates for erecting a building behind the news-room for the reception of the electrical machinery. The committee have taken this course on the suggestion of Mr. Barton, the electrical engineer, who advised them to have the electrical machinery in a structure outside the main building.

Warning.—We hear of several cases of a person who passes as a representative of well-known firms and obtains goods in their name without any authority. Messrs. Edmundsons, Limited, 19, Great George-street, Westminster, inform us that they have had several such instances brought to their notice quite recently, and wish to warn all firms not to supply goods to anyone without their official order.

City of London Company's Dividend.—The directors of the City of London Electric Lighting Company, Limited, have declared an interim dividend on the preference shares of the Company at the rate of 6 per cent. per annum, for the six months ending June 30. The dividend will be payable on and after the 19th inst. The warrants for the interest due June 30 on the debenture stock have been posted.

Wimshurst, Hollick, and Co., Limited.—This Company has been registered with a capital of £40,000 in £5 shares, to carry into effect an agreement between T. D. Hollick, Sidney Hollick, and F. W. Drake, and this Company, for the acquisition of the business of electrical and general engineers and boilermakers now carried on by Wimshurst, Hollick, and Co. at 602-604, Commercial-road, London.

Rochdale.—A bazaar has been held at Mount Falinge, a large residence in this town, on behalf of the building fund of Providence Chapel. There was a temporary installation of the electric light, which was carried out by Mr. J. K. Grindrod. Each room of the house was lighted with incandescent lamps, and outside there were two arc lights. A dynamo driven by a portable engine was employed.

Derbyshire.—It is mentioned in the forty-second annual report of the Derbyshire County Lunatic Asylum that, in connection with the matter of lighting, the question of electric installation has been under consideration, a special report dated December 6 last having been obtained from Mr. A. H. Preece, 39, Victoria-street, Westminster, London, who inspected the asylum and went fully into the subject.

Wolverhampton.—A start was made not long ago with the new municipal electric lighting works, which are situated in Commercial road, and within a few months the new illuminant will be in use in the principal thoroughfares and public buildings. The mains have been laid down as far as Dudley-street and Queen-square, so that in a short time the centre of the town at any rate will have been provided for.

Dissolution of Partnership.—The partnership subsisting between William Thomas Burbey, Albert Edward Williamson, and Edward Lionel Joseph, as electrical engineers and manufacturers, at 92, Queen Victoria-street, and at Church-street, Horsley-down, has been dissolved by mutual consent so far as regards William Thomas Burbey. The business will be continued by Albert Edward Williamson and Edward Lionel Joseph.

Cheltenham.—On Monday, Mr. H. Kilgour was appointed electrician to the Town Council, at a salary of £200, rising to £250. Messrs. Malvern's tender at £1,799 was accepted for the erection of the central electric lighting station. The tender of Callender's Bitumen Telegraph and Waterproof Company at £1,031. 8s. 4d. was accepted for the supply of cables, subject to the high-pressure cables being guaranteed for 10 years.

Ilfracombe.—At a meeting of the Local Board on Monday the Great Western Light and Power Company, Limited, intimated their intention to apply for a provisional order to enable them to supply electricity to the district. Mr. Prouse (surveyor) said the Board ought itself to obtain the order, and if they did not care about supplying the electricity they could lease their rights to a company. It was decided to oppose the provisional order.

The Phonograph Action.—In the case of the Edison-Bell Phonograph Corporation, Limited, *v.* the London Phonograph Company, Mr. Justice North has granted an injunction restraining the defendants from infringing the plaintiffs' patent for phonographs. His Lordship said that Mr. Justice Wright had already held that the plaintiff's patent was valid, and, admittedly, there had been infringement of two of the claims in the specification.

Kingston-on-Thames.—The Lighting and Market Committee reported to the Town Council last week that the town clerk had submitted a letter from the Local Government Board in regard to the application for the further loan of £6,000 for electric lighting purposes, stating the particulars that would be required for the Board's consideration, the same to include the plans and estimates. The consulting engineer submitted the estimates, and was instructed to prepare the necessary plans.

Digitized by Google

Harrow.—A petition, signed by 109 ratepayers, has been presented to the Local Board by Mr. O. A. Saunders on the subject of electric lighting, asking that before any proceedings were taken the Board would call a public meeting. It appears that the Board has no power to spend money in calling a public meeting. It was therefore suggested that a deputation from the signatories should be asked to meet in the Board-room, when the matter could be explained. This suggestion was carried.

Case of Appeal.—In the Judicial Committee of the Privy Council, on Saturday, judgment was given in an appeal of the Winnipeg Street Railways Company from a judgment of the Court of Queen's Bench in Manitoba. The point really at issue was whether the appellant company were entitled to the exclusive right of constructing railways in the streets of the city of Winnipeg, and their lordships, concurring with the Manitoba Court that they had no such right, dismissed the appeal, with costs.

New Branch.—The Electrical Installation Company, Limited, of 66 and 64, Victoria-street, S.W., have recently completed an installation for Lord Stratheden and Campbell at his seat in Roxburghshire, the dynamo being driven by water power, and supplying not only the house and stables and a battery of Epstein cells as a reserve, but also providing the current if required during the day for an electric motor erected at the home farm. The Company have opened a branch in Edinburgh at 30, St. Andrew-square. Mr. J. H. Mackail is their district engineer for that city.

Eccles.—The elective auditors of the Town Council, in the course of a comic report on the finances of the Corporation, say: "Over £600 has already been spent in furtherance of the project of electric lighting. Boroughs with greater funds at their command have left this luxury alone, and it is worth considering seriously whether any further expense should be incurred in this direction." The elective auditors apparently do not quite understand what their function is. A number of members of the Town Council protested against the tone adopted in the report.

Wrexham.—At a meeting of the Town Council, on the motion of the Mayor, seconded by Mr. Charles Davies, the corporate common seal was affixed to the joint memorial from the Wrexham and District Electric Supply Company, Limited, and the Corporation to the Board of Trade, in reference to the proposed acquisition by the Corporation of powers of electric lighting within the borough, with the sanction of the Board of Trade, by provisional order, license, or otherwise, and applying that the Corporation might become the undertakers for such supply in the place of the company. It was stated in the memorial that the price to be paid is £350.

Folkestone.—A special meeting of the Council has been held to consider an application from the Brush Provincial Electric Lighting Company, Limited, as to whether the Corporation would sanction an application by the company for a provisional electric lighting order. The Corporation would have the option of acquiring the company's property on agreed terms, at the expiration of seven, 14, or 21 years. The Town Clerk stated that the Board of Trade would not entertain any such application by a private company without the consent of the Corporation, except in very special circumstances. After a good deal of discussion, a resolution was carried that the Brush Company be informed their request cannot be granted, as the question of the adoption of a scheme by the Corporation is still under consideration.

A Question of Wages.—A deputation was received on Friday by Mr. Arnold Morley, the Postmaster-General, from the London Trades Council, and representatives of the Scientific Instrument Makers and Electrical Trade Union. Mr. G. Shipton, of the London Trades Council, in introducing the deputation, said they wished to draw the attention of the Postmaster-General to the low rate of wages paid in the Department's workshops, and also to the general treatment meted out to the employés as compared with the conditions under ordinary employers in these industries. The union representatives spoke at length on their grievances, and Mr. Morley, in promising that the whole question should have his careful consideration, said it was his desire that all the departments should be managed on strictly fair conditions, as he was of opinion that the State should be a model employer.

Bournemouth.—At Tuesday's meeting of the Town Council, letters from Mr. J. S. Raworth, manager of the Brush Electrical Engineering Company, Limited, were read at the meeting of the Roads Committee, asking permission to fit three or four of the existing street lamps with incandescent lamps of various candle-power to be supplied with current from the transformer station near the Arcade. The experiment is to be made with low-tension current, and not to involve taking up the roadway for inspection by the Town Council of Winchester, with whom they were negotiating for lighting that city. A letter from Mr. Bailey, town clerk of Winchester, was also read, stating that the Corporation of Winchester would feel obliged if this Council would permit the experiment to be made. It was recommended that permission be given subject to the details being arranged with the surveyor after consultation with the chairman of the Lighting Committee. The proposal was agreed to.

Baxendale and Co.—This Manchester company inform us that, among other contracts, they have recently received the following: Denbigh Lunatic Asylum, telephonic communication; Messrs. J. and R Brown, Manchester, incandescent lighting; Mrs. Astin, Manchester, incandescent lighting; similar illumination at the Manchester Pantechnicon; and incandescent lighting at Mr. M. S. Shepley's, Oldham, and at Stirling and Co.'s, Manchester; Slater's Directory Offices, Manchester, incandescent lighting; telephonic communication at Messrs. Bartlett and Co.'s, Manchester, and at Messrs. Bancroft and Co., Manchester; and arc lighting the North Pier, Blackpool. The last-named work is being carried out with concentric wiring, the cables employed being of the well-known paper-insulation class, manufactured by the British Insulated Company, of Prescot. The arc lamps are of the Brockie-Pell standard type, complete with hood and lamp-carrier attached to ornamental standards.

Conversion of Debenture Stock.—The National Telephone Company, Limited, announces the conversion and redemption of £1,000,000 4½ per cent. debenture stock by the issue of £1,100,000 of 3½ per cent. debenture stock, forming part of a total amount of debenture stock which is limited to £2,000,000. All outstanding 4½ per cent. debenture stock of the company not presented for conversion will be repaid and cease to bear interest from December 31, 1894. The directors invite subscriptions for the above £1,100,000 stock on the following terms: existing 4½ per cent. debenture-stock holders will receive allotment in full, at the rate of £110 of the new stock for every £100 of the old stock and 6s. 6d. in cash (less tax) per £100 existing stock upon allotment (being the difference in interest for the half-year ended December 31, 1894, between £110 stock at 3½ per cent. per annum and £100 stock at 4½ per cent. per annum), thus making up the half-year's interest to 4½ per cent. per annum.

Larne.—The principal business before the Town Commissioners on Monday was the approving of the agreement between the Commissioners and Messrs. J. E. H Gordon and Co. The contractors agree to light the town with electric light for three years from August 1, 1894, by means of 11 1,200-c.p. arc lamps, at £11 each per annum; six incandescent lamps of 32 c.p., £4 each per annum; 66 incandescent lamps, 16 c.p., at £2 each per annum, they to provide and pay the necessary staff for regulating and maintaining the lamps and the lighting of the town during the contract, and shall maintain the lighting in a state of efficiency from dusk to midnight from August 1, 1894, till the last day of the succeeding April. Mr. Picken remarked that there was no penalty clause in the agreement. Mr. English moved that the agreement be signed. After discussion Mr. Picken moved that the agreement be not signed until the penal clause is reinserted—*i.e.*, that clause 8 therein be made a penal clause. This was seconded, and on being put was declared passed.

The Rhondda Valley.—According to a Rhondda correspondent, the extensive collieries of the Ocean Company, situate in the vicinity of Treorky, have been partially lighted with electricity for 10 years. The Park Pit is lighted on the surface and also below. At the Dare Pit there is a separate plant. From the latter a private line leads current to the village of Cwmpark, where the road is lit up by 25 lamps. Two chapels have each 21 lights of 16 c.p, while the Board schoolroom is provided with 16 lights. A few of the houses in the village are also lighted electrically. Mr. B. D. Williams, the company's electrician, when not engaged in attending to the plant, has, it is stated, his hands full of work in preparing such things as portable electric light lamps of various sizes and shapes, and other appliances which are invaluable in places where the safety of life and limb is so carefully looked after. Mr. Williams points out that the time cannot be far distant when colliery companies will generally adopt the principle of the lighting of mines by electricity, which, in addition to giving a better illuminant, will render explosions caused by flames impossible.

Burton.—At a meeting of the Town Council on Wednesday, in the report of the Gas and Electric Light Committee, the chief recommendations were to make a grant of £100 to Mr. Ramsden, gas manager, for his services in designing and constructing the electric light works, and to make him manager of the latter at a salary of £50 per annum, dating from February last. Alderman Lowe, in moving the adoption of the report, claimed that Mr. Ramsden had saved them at least £1,000 by acting as engineer for the construction of the works, and that if they appointed an independent manager of the electric light they would have to pay at least £250 a year, whereas it was now proposed that they should only pay £50. Councillor Turner seconded the motion, but Councillors Graham, Thurnley, and Austin offered opposition, and amendments were moved to the effect that an honorarium of £150 should be given for the additional services, and that the question of salary should remain in abeyance until March next, when salaries have to be raised. A further amendment was made that the honorarium should be £50, and that the salary should be £25 per annum, but only three voted for each amendment, and the original proposition was carried.

Aberdeen.—A meeting of the Watching and Lighting Committee of Aberdeen Town Council was held on Saturday—Bailie M'Kenzie presiding—to consider the lighting arrangements of the new police offices. It had been proposed to introduce the electric light, and also the usual gas fittings. The Convener made an explanation regarding his statement at the Town Council meeting to which we have already referred, that the electrical engineer had advised the city architect to have the gas pipes fitted up. It had been reported that, at a subsequent meeting of the Gas Committee, Mr. Murray said he had not given such advice to anybody; but the city architect now explained that he asked Mr. Murray's advice as to whether the gas-pipes should be taken in when the electric light was to be introduced, and that gentleman's reply was that as the contractor for the gas fittings would likely have to be paid in any event, they would be as well to have the pipes taken in. Mr. Murray, who was present, admitted having given such advice under the impression, as he explained, that the fittings would have to be paid for even if they were not put in:

Digitized by Google

but neither he nor Mr. Rust had any doubt as to the sufficiency of the electric light by itself. The Convener then asked if it was the mind of the meeting to have the buildings fitted up throughout with the electric light and no gas fittings introduced, and this was unanimously agreed to.

Hastings Accepted Tenders.—The following tenders were received for electric light wiring at the Queen's Hotel, Hastings, for the Queen's Hotel Company, Limited, Hastings:

Spiers and Pond, London	£510	0	0
Belshaw and Co., London	448	0	0
Hastings Electric Light Supply Company	358	13	4
Strode and Co., London	343	0	0
Roger Dawson and Co., London	300	0	0
Raynes, Smith, and Co., London	269	10	0
Fowler, Lancaster, and Co., Birmingham	265	0	0

The tender of the Hastings Electric Light Supply Company was accepted. For electric light fittings and fixing at the Queen's Hotel, Hastings, for the same company, the tenders were as follows:

J. Barker and Co., London	£411	0	0
Strode and Co., London	346	11	0
Hastings Electric Light Supply Company	345	18	4
Hands, London	310	9	9
Verity and Co., London	306	19	0

Burnley.—The fourteenth annual report of the Burnley Corporation officials has been issued, in which Mr. F. Thursfield, the electrical engineer, says: "It is satisfactory to be able to record that the demand for electricity has already reached, if not exceeded, the first expectation. When the canvass of the borough was made in the beginning of 1892, 32 persons signed forms undertaking to receive a supply for a total of 2,732 lamps of 8 c.p., or their equivalent. Out of these 17 only have at present become consumers, with a total of 763 lights; leaving 15 consumers who have yet to make good their promises, and add 1,609 lights to the mains. In addition to this, there are six others who signed the forms undertaking to receive a supply, who did not state what their requirements would be, and who have not yet taken any steps in the matter. So that if you had only to rely on the result of this canvass the business would be in anything but a flourishing condition. On the other hand, 51 additional consumers have been induced to come forward since the plant has been started, and they are now taking a supply for 3,592 lamps. You will see from the estimates for the coming year that a working profit of £570 is anticipated. This will probably pay about half of the interest and sinking fund due from this department; so that there is reason to hope that as soon as the output is doubled the business may be able to show a satisfactory balance-sheet, as the working expenses should scarcely increase in the same proportion."

Lighting of the City.—On Tuesday, at a meeting of the Commissioners of Sewers, Mr. Turner asked for information on the subject of two recent failures of the electric light, and moved that a return of all such failures should be placed on the table at each meeting of the Commission. This proposition having been seconded, was carried. The Engineer said he had some information as to a failure of the electric light on the 12th ult., when 11 lamps failed, and it was reported to be due to the fact that some oil had run on the carbon, and it had not been noticed by the lamp trimmer. The other failure, on the 14th ult., was due to the breaking of a lamp. At the same meeting, the following resolution by Mr. Gordon was adjourned until the next court: "That the resolution of this Court of July 25, 1893, agreeing to a recommendation of the Streets Committee that the Commissioners only consent to the use for telephonic purposes of certain tubes laid by the City of London Electric Lighting Company on a guarantee being given that telephones, with double wires and all the latest improvements, will be supplied to the citizens at a cost not exceeding £8 per annum, be rescinded, and that an offer of the said company to pay the Commissioners '10 per cent. of any annual rental, so long as such may be received for the use of any tubes for telephonic purposes, up to a sum of £10,000 per annum, and 20 per cent. on any rental in excess of £10,000,' be accepted, provided the minimum amount to be received by the Commissioners be £1,000 per annum, and subject to a proper agreement being entered into with the company, without prejudice in any way to the rights and privileges of the Commissioners under the contracts and provisional orders."

Fleetwood.—At the ordinary monthly meeting of the Improvement Commissioners, the Highway, Lighting, Fire Brigade, and Building Committee recommended unanimously that the correspondence with Messrs. Carrick and Ritchie, Edinburgh, be approved, and that their offer of a five-ton crane, erected and completed in the proposed electric lighting station, for the sum of £82, be accepted, subject to the usual conditions as to contract, sanction for borrowing powers, etc.; also that the tender received from Mr. Jonas Kirkbride for erection of new buildings, etc., in the town's yard, be increased by the sum of £10 for additional ironwork in the roof of engine and generator rooms as per amended plan now produced, and letter dated 29th ult, was read from the Brush Electrical Engineering Company, Limited. The amount of tender as now amended is £2,024. 12s. 7d. The committee further recommended that the clerk be authorised to apply for sanction to borrow the requisite sums of money required in connection with the proposed installation of electric lighting in this district, as per estimate to be submitted to the Board at the next meeting; that the tender of the Brush Electrical Engineering Company, Limited, for electrical plant, etc., be increased by the sum of £150, as under: special stoking arrangement for generators as inspected at Coatbridge, £100; preparing plans for buildings, £50; the total tender being £8,850; and that the said tender (as amended) be accepted on the usual conditions as to contract, sanction for borrowing powers, etc. Mr. C. Drummond wrote accepting the position of engineer in connection with the proposed new buildings in the town's yard, and it was recommended that the appointment of Mr. C. Drummond be approved.

The Leeds Tramways.—The first result of the visit paid to Newcastle, Edinburgh, and Glasgow by the members of the Leeds Corporation Tramways Committee, and to which we referred in our last issue, will be the presentation of a report on the subject of tramway haulage. The committee have not agreed upon any recommendation on the subject; they did not get back to Leeds until Thursday of last week; but the town clerk (Mr. John Harrison) and the city engineer (Mr. Hewson) are in possession of a mass of information, legal, technical, and general, upon which they will shortly be prepared to advise the committee and through them the Council. The committee were absent from Leeds three days, Newcastle being visited first. Here they were received by Councillor H. Morton, chairman of the Newcastle Tramways Committee, and had explained to them the position of the Corporation in regard to the proposal to adopt the cable system, besides having the opportunity of surveying some of the existing lines. The points urged in favour of the cable system in Newcastle were that, notwithstanding its costly nature, it would prove thoroughly efficient, and could be economically worked, whilst providing for a very complete service and being well adapted for heavy traffic and stiff gradients. The estimated cost per car mile was said to be about 4½d., as compared with 8½d. for an electrical service on the basis of the Budapest conduit electric system, and 10d. for horse traction. The Leeds committee had not time to stay and accept the full hospitality of their Newcastle hosts, and after having simply partaken of light refreshment, they hurried on to Edinburgh, where they were shown over the Golden Acre cable line, and inspected the Stockbridge section. One of these routes leads to a pleasant residential suburb, and the other serves a poorer district of the city. During the day the visitors were entertained by the Lord Provost and members of the Edinburgh Corporation at the Royal Hotel, and had the privilege of viewing the Corporation buildings. On their arrival the previous evening they drove out to the Forth Bridge, in the company of Mr. John Kerr, of Dick, Kerr, and Co.

Elmore's Patent Copper Depositing Company.—The directors summoned a meeting of the shareholders, which was held at the Cannon-street Hotel, yesterday, for the purposes of receiving their resignation, and appointing new directors in their place. The directors stated in the circular convening the gathering: "It will be in your recollection that the Investigation Committee recommended, in the first instance, that local directors should be selected; but that being impossible at the time, the present directors were appointed. Their work has been done at much inconvenience to themselves, to the best of their ability in the interests of the shareholders; but they feel it most difficult to exercise a proper control over the business without a sacrifice of time which their other occupations render most inconvenient. They are desirous, therefore, of placing their resignation in the hands of the shareholders, and are, they believe, fully justified in so doing under the conditions which are such as will enable them to present to the meeting the names of local gentlemen of position and ability who are now willing to take over the direction of the Company's affairs. It will be evident that the position of the business and condition of the works must be greatly improved, or the proposed new directors would not have been induced to come forward and take a large pecuniary interest in the business, and place themselves in the responsible position of controlling the affairs of the Company. After the last meeting £10,000 of 6 per cent. debentures were offered to the shareholders, but as the issue met with little response, the deposits were returned. The want of capital caused again delay in developing the business, and it was only after some time that an arrangement was come to with our bankers (through the agency of Mr. William Elmore and the guarantee of Mr. A. S. Elmore) to the extent of £15,000. This provides for the purchase of ample supplies of copper and the completion of the needful plant, so that nothing should now be wanting for the accomplishment of profitable results. The Wire Company having obtained capital, an arrangement must now be made with them for the joint use of the furnaces, and as other important agreements are waiting completion, my directors are desirous that they should be entered into by the new directors, who would then commence their duties with a fuller control of the interests of the business."

Hull.—At a meeting of the Corporation Electric Lighting Committee Mr. A. H. Gibbings, the electrical engineer, presented a report with reference to his previous report respecting oil fuel. He stated that he had visited the works of Messrs. W. S. Laycock and Co., Government and railway stores contractors, Sheffield, where he inspected three boilers, each fitted with Holden's apparatus for burning oil fuel. The steam for the injector was taken immediately from the face of the boiler in a similar way to the arrangement which he fitted up on one of the boilers for minimising the amount of smoke at the time of heavy firing. Messrs. Laycock and Co. obtain their oil fuel, which was creosote, from chemical works and different sources of supply about the neighbourhood, and they found that at 1s. 4d. per gallon it was equal to coal at 12s. per ton. He described the system of working, and, in concluding, said Messrs. Laycock's figures with reference to the comparative cost of oil fuel and coal were the same as those he mentioned at the last meeting. He was of opinion that oil fuel would be economical at any price not

Digitized by Google

exceeding 1d. per gallon. He recommended the committee to fit up one boiler with Mr. Holden's apparatus when a favourable opportunity occurred, which would not be until he was able to bring before the committee some definite proposal with reference to the supply at an economical price of the necessary fuel. A report was read respecting an application from Walthamstreet Chapel to be supplied with electricity. The Chairman (Mr. Holder) expressed the opinion that places of worship might be placed on more favourable terms than places of business. It would be worked at a time when there was no maximum demands by the large shops. He moved "That, inasmuch as the Sunday demand for electricity will, as winter approaches, require a Sunday shift of workers at the station, and as such a shift can work the whole machines as easily as it can one, it is desirable to foster the demand for the light for illuminating churches and chapels. As an inducement, this committee recommend the Council be asked to supply places of worship requiring the light at a charge of 5½d. per unit for such electricity as they may use in such places or in the class of rooms attached thereto." Alderman Fraser seconded the resolution, which was dissented to by Mr. Millington on the ground that it would interfere with Sunday labour.

Tenders Accepted for Bedford.—The Urban Sanitary Authority met last week to consider the report of the Electric Light Committee recommending the acceptance of certain tenders for buildings, machinery, and plant in connection with the installation of the electric light in Bedford. The following is the list of the tenders that were sent in :

	£	s.	d.
Mains and Transformers.			
Pritchetts and Gold	3,465	10	0
Porter and Harrison	3,350	0	0
New and Mayne	3,282	2	6
Brush Electrical Engineering Company, Limited	3,068	0	0
Electric Construction Company, Limited	2,780	0	0
British Insulated Wire Company, Limited	2,686	10	5
India Rubber, Gutta Percha, and Telegraph Company Limited	2,598	0	0
J. Fowler and Co., Limited, Leeds	2,560	0	0
Glover and Co.	2,520	15	0
Henley's Telegraph Works, Limited	2,463	16	8
Hooper's Telegraph and Indiarubber Works, Limited	2,450	0	0
Johnson and Phillips, London	2,416	4	0
Crompton and Co., Limited	2,333	0	0
Telegraph Manufacturing Company, Limited	2,271	5	2
Siemens Bros. and Co., Limited (incomplete tender)	2,215	0	0
Plant.			
Barley, Grundy, and Barrett	9,320	0	0
Siemens Bros. and Co., Limited	6,290	0	0
J. Fowler and Co., Limited, Leeds	6,123	0	0
Brush Electrical Manufacturing Company, Limited	5,890	0	0
Crompton and Co., Limited	5,791	0	0
Allen, Son, and Co., Bedford	5,731	0	0
Electric Construction Company, Limited	5,317	0	0
Johnson and Phillips, London	5,200	0	0
Buildings and Shaft.			
G. E. Fathers, Bedford	2,022	13	6
J. J. Potter, Bedford	1,911	0	0
T. H. Coleman, Bedford	1,565	0	0
Travelling Crane.			
Bedford Engineering Company	120	0	0
Grafton and Co., Bedford	85	0	0

The tender of the Telegraph Manufacturing Company, Limited, was accepted for the mains and transformers; that of Messrs. Johnson and Phillips for the plant; that of Mr. T. H. Coleman for the buildings and shaft; and that of Messrs. Grafton and Co., for the travelling crane.

Manchester.—A report of the Electric Light Department of the Manchester Corporation for the year ended March 31, 1894, was submitted to the Council at its meeting on Wednesday. The buildings, boilers, engines, dynamos, and other plant referred to in the report of last year have been completed, and the supply of current was commenced on July 31, 1893. The number of consumers at the close of the year was 412, and the number of incandescent lamps in use was 18,478, arc lamps 250, and 11 motors representing 16 h.p. The total quantity of current supplied and charged for was 439,379 units, and the amount of revenue from both methods of charge, including fixed charge per lamp and rate per units consumed, was £10,067. 7s. 4d., which works out to about 5½d. per unit. The amount for which borrowing powers have been obtained is £150,000, and of this sum £127,830 has been borrowed. The amount of capital expenditure to March 31, 1894, less £610. 16s. 3d., being interest on loans during construction transferred to revenue account, was £127,374. 11s. 4d. The total amount of revenue from sales of current and rental of meters was £10,198. 11s 7d. The cost of generation, distribution, and management, as set forth in abstract No. 3, was £5,509. 16s. 4d., to which amount must be added for interest from the commencement of the undertaking, £3,461. 6s. 7d.; bankers' commission, £60. 9s. 11d.; and sinking fund, £1,376 17s. 7d.; leaving a debit balance of £209. 18s. 10d. to be carried forward to next year's account. The generating plant in operation was estimated to supply an average of about 20,000 16-c.p. incandescent lamps, and to be quite equal to any demand which would be likely to be made upon it for two years or more. So numerous, however, have been the applications that the plant is already loaded to its full capacity, and it was found that without extension there would be difficulty in fully supplying the demand for next winter. Under these circumstances it was decided to extend the plant by the following—namely, one Lancashire boiler, two 360-h.p. vertical compound condensing engines, and two large dynamos. These works are now in progress, and will be available for next winter. The new offices, workshops, and storerooms are also rapidly approaching completion. The applications for a supply of current outside the present area are so numerous that the committee have decided to make enquiry, and on a future day to report to the Council as to the desirableness of laying mains in certain leading thoroughfares, and of providing the additional plant and machinery required to generate the current, for which there is every probability of a great demand.

Canterbury.—A public meeting has been held at Canterbury under the presidency of the Mayor to consider the question of the introduction of the electric light. The Mayor said that the question of electric lighting had for a long time exercised the minds of the citizens, they having obtained their provisional order at a cost of £450, and offered the same to the Brush Company. It appeared now, however, that other conditions as to the capital must be complied with, and those conditions would be laid before the meeting by the company's representatives. He was sure they would all listen with interest and attention to the representatives of the company present, and he would at once call upon Mr. Sellon to address them. Mr. R. Percy Sellon said that the company entered into the negotiations with a great deal of enthusiasm, believing strongly that the electric light at Canterbury would be a first-class success, not only from the investor's but from the consumer's point of view. However, when they came to take steps to issue the prospectus, they found a certain amount of apathy towards the undertaking, and on instituting a canvass in the town, the result was not assuring to them of that minimum amount of demand for the light which was essential for them to start with. Therefore, local opinion in the past had been responsible for a considerable amount of delay. The Corporation had met them in a generous and fair spirit by granting an extension of the time so that they could satisfy their minds clearly as to local support. That extension was now drawing to a close, and it was well, they would agree, to bring the matter to a head at once. The last 10 years' experience had established the fact that the installation would not pay the investor unless there was a demand for between 3,000 and 5,000 lamps, in order to pay a dividend to the shareholder. The company were perfectly willing to provide two-thirds of the capital required, whatever the amount might be, provided local people would come forward with the remaining third. Reducing this to figures, he might say that the installation, paying a reasonable sum for land, building, and plant, would involve an outlay of about £18,000—not less than £15,000 and not more than £20,000—so that the company would find £12,000 if Canterbury would provide the balance of £6,000. On the motion of Councillor Lukey the following resolution was adopted : "That in the opinion of this meeting it is desirable that the electric light should be forthwith introduced into the city, and that a committee, consisting of the following gentlemen, be formed—Mr. Sellon and Mr. Lawson, of the Brush Company, the Mayor, Alderman Mount, Alderman Mason, Mr. F. Wacher, and Councillor Lukey—to ascertain how the necessary capital can be raised and to ascertain the probable number of customers when it is introduced."

Southampton.—At a meeting of the Town Council, the Works Committee reported the receipt of a letter from the Southampton Electric Lighting Company relative to their undertaking, and it was resolved that this committee was of opinion that it is desirable to enter into negotiations with the electric light company for the purchase of their undertaking, and for this purpose recommend the Council to appoint a committee to confer with the directors relative thereto. Mr. Lemon proposed the adoption of the report, stating that the committee were of opinion that it was desirable to enter into negotiations with the electric light company for the purchase of their interest, but the company said, and very properly, that they were not prepared to show their accounts unless the Corporation had made up their minds whether they would purchase or not, and the committee asked for the approval of the principle, subject to fair and reasonable terms being obtained. If they considered it was not desirable to purchase the interest of the company on any terms, they had better say so, and no further steps would be taken. If the Corporation approved of the principle that the interest of the company should be acquired, they asked for a committee to be appointed to confer with the directors of the electric light company to see if they could come to terms, and if they did they should report and ask the Council to consider it. The Council would not be bound by adopting the report, but were asked to say yea or nay whether they would affirm the principle. The matter came before the Corporation in 1890, when it was proposed to purchase the provisional order for £750, but it was negatived by a large majority. He was strongly of opinion that everything of the character of these works should be in the hands of the Corporation and not of a private company, but of course it was a question of price, and he hoped if the Corporation could see their way they would give instructions to do as the committee recommended. Mr. Kitcher seconded the proposition. The Town Clerk read a correspondence in connection with this matter, including a letter from Mr. J. T. Hamilton, secretary to the company, dated June 7, as follows : "Dear Sir,—Your letter of the 23rd ult. was considered by my Board at their meeting yesterday. I am desired by them to say that if the Corporation are seriously taking into consideration the question of purchase they will appoint a committee to meet a committee of the Corporation in order to discuss the whole matter.' Alderman Payne remarked that this was a very serious matter, and ought not to be hurried over. If they had purchased the gasworks the town would have made thousands every year by the transaction, and have had money to build a town hall. The

Digitized by Google

present matter would be a gigantic affair, and as they were over head and ears in debt he hoped those favourable to making the purchase would not do so unless they could show that the town and ratepayers generally would benefit. Alderman Gilbert said that he was fully in sympathy with the idea that the gas and electric lighting concerns should be in the hands of the Corporation, but the matter was fully discussed in 1890, and they did not like to pay £700 or £800 for what was given away. He objected to the principle of purchase before they went into details as to the price. He agreed with the principle that it was a wise thing for the Corporation to keep anything in their own hands which was likely to be a monopoly, but they ought not to go further until they had more details before them. The Town Clerk pointed out that it was open to the Corporation to apply for a provisional order, and he suggested that it might be referred to committee to discuss the whole subject. Mr. Walton remarked that the company wanted a guarantee, and it would be unfair to ask them to open their books unless they had a real intention to proceed to business afterwards. Mr. Lemon agreed with the suggestion, stating that the contention of the company was only fair and reasonable. It was only a question of price, and could not do any harm to refer it. The subject was then referred back to the committee.

PROVISIONAL PATENTS, 1894.

JUNE 25.

12241. **Electromagnetic traction.** John Perry and Thomas Tomlinson, 31, Brunswick-square, London.

12253. **Electric staff and tablet detector.** Henry Powis and George Evans, 22, Benyon-street, Shrewsbury.

12283. **Improved block system on electric railways and apparatus therefor.** Eugen Langen, 28, Southampton-buildings, Chancery-lane, London.

12304. **Improvements in and relating to electric telephone systems.** Henri Noël Frenay-Olyff, 45, Southampton-buildings, Chancery-lane, London.

JUNE 26.

12313. **Improvements in or in connection with arc lamps.** Frank Michael Lewis, 2, East-parade, Leeds.

12345. **Improvements in transformer systems of electrical distribution.** Peter Wright, 323, High Holborn, London. (Complete specification.)

12349. **Improvements in or relating to heating metals electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

12400. **Improvements in regulators for electric arc lamps or lighting apparatus.** François Suisse and Paul Eugéne Hennequin, 11, Southampton-buildings, Chancery-lane, London.

12406. **Improvements relating to electric and other motors.** Thomas Ernest Waltham, 24, Southampton-buildings, Chancery-lane, London.

12407. **Improvements in cable transmitters.** Herbert Taylor, 24, Southampton-buildings, Chancery-lane, London.

12411. **Electric igniting device suitable for lighting tobacco-pipes and cigars.** Friedrich Wilhelm Schindler, 433, Strand, London.

JUNE 27.

12476. **Improved system of switching and regulating apparatus for central stations for the generation and distribution of electrical energy.** John Smith Raworth, 46, Lincoln's-inn-fields, London.

12483. **Improvements in or connected with electric batteries.** Charles Percy Shrewsbury, Frank Lawrence Marshall, John Cooper, and John Laskey Dobell, 57, Chancery-lane, London.

12492. **An improved construction of holder for incandescent electric lamps.** William Underhill Hilliar, 6, Bream's-buildings, Chancery-lane, London.

12505. **Improvements connected with arc lamps.** John James Rathbone and Arthur Chester, 166, Fleet-street, London.

12510. **Improvements in apparatus for supplying electricity to electrically-propelled vehicles.** Emile Chabeault, 46, Lincoln's-inn-fields, London.

JUNE 28.

12541. **Improved apparatus for intermittent measurements of alternating currents.** Francis Henry Nalder, Charles William Scott Crawley, and Alfred Soames, 16, Red Lion-street, Clerkenwell, London.

12549. **Improvements in cables for telephonic and telegraphic purposes.** Moritz Immisch, 52, Chancery-lane, London.

12552. **Improvements in protecting, and in fittings for connecting lead-covered or other armoured electric cables with naked or other conductors.** George Hinde Nisbett, 6, Lord-street, Liverpool.

12557. **A system of luminous electric skipping-rope.** Gustave Trouvé, 53, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, sec. 103, June 18, 1894, being date of application in France.)

12566. **A dust-proof electrical switch.** Albert Edward Williamson, 77, Chancery-lane, London.

12605. **Improvements in or in connection with long-distance telephones.** Wasili Alexandrowicz Nikolajczuk, 34, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JUNE 29.

12620. **Improvements in electric arc lamps.** Job Thomas Niblett and Malcolm Sutherland, 20, Devonshire-road, Greenwich, London.

12650. **Improvements in storage battery plates.** Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster.

JUNE 30.

12707. **Improvements in or connected with electric lamp-holders, sockets, or connections.** John Benjamin Verity, Plume Works, Aston, Birmingham.

12748. **Improvements in mounting electric and other lamps.** William Newbigging, 55, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1891.

9079. **Electrolytic extraction of metals.** Hoepfner. (Second edition.)

1893.

11168. **Arc lamps.** Death.

11294. **Electric exchange.** Pippette.

13217. **Electric batteries.** Lithanode and General Electric Company, Limited, and Niblett.

14562. **Alternate-current dynamos, etc.** Ravenshaw and Atkinson.

14969. **Dynamos, motors, etc.** Newton and Hawkins.

15073. **Electric arc lamps.** Cooper and others.

16025. **Electromotors.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

1894.

1849. **Arc lamp.** Taylor.

4429. **Electrical switches.** Metzger.

5158. **Splice coverings for electric wires.** Dewees.

7239. **Electric motors.** Coerper.

8835. **Electrical propulsion of cars.** Still.

8917. **Electro-deposition of metals.** Alexander.

NOTES.

Electric Traction at Mulhouse. — The electric tramway here is nearly ready for opening.

Aschaffenburg.—A provisional electric light installation has been started for the lighting of the railway station.

Nyasaland.—The construction of the telegraph is now making rapid strides, and the line will reach Zomba by the end of June.

Electric Traction at Abazzia.—The Austrian Ministry of Commerce has given a concession for an electric railway from Abazzia *viâ* Ika to Lovrana.

The Blackfriars Accident.—A verdict of accidental death has been returned in the case of A. Bungay, who received a fatal shock at the Blackfriars transformer station.

Street-Lighting at Leipsic.—The Municipality are having 50 electric lamp-posts made for street-lighting at a cost of £1,050. The municipal budget provides £1,400 for maintaining these lights.

Electric Lighting at Schneidemuhl.—It is proposed to establish a central electric light station at Schneidemühl. Subscribers have been obtained for 500 incandescent lamps, 30 arc lamps, and five motors.

Glasgow Technical College.—The governors of the Glasgow and West of Scotland Technical College have applied to the Treasury for a share to this college of the grant to university colleges in Great Britain.

Not Sheet Lightning.—Lightning has been playing havoc during the past week. It has killed men, poultry, and dogs. If it had been the "yaller dog" it would not have mattered; it's got the jaundice bad enough.

On the War Path.—The *Cable Gazette*, without taking the trouble to ascertain its facts, last week credited Mr. A. Dickenson with reading a paper before the Tramways Institute. Better leave the agenda alone next time.

Telephony at Fiume.—The Fiume Chamber of Commerce are petitioning the Hungarian Minister of Commerce to establish a telephone line between Fiume and Budapest, and ultimately between Fiume and Trent.

Electric Lighting at Neutich.—The proprietors of the Neutich Sugar Refinery, West Prussia, are going to light the whole of their works electrically. They also propose to supply current to the town and to other works.

Gas Amenities.—At a meeting of the Wolverhampton Town Council, the Mayor stated that he had received what he styled "a scurrilous letter" from a gas firm with regard to his statement as to the cost of electric lighting.

An Electric Ballet.—At the Winter Gardens, Blackpool, Mr. William Holland is presenting a "Carnival Electrique," in which electric lights of a total of 35,000 c.p. are employed. The electrical effects have been devised by M. Collet, of Paris.

Electric Traction at Genoa.—The Allgemeine Elektricitäts Gesellschaft, of Berlin, have acquired the Bucher concession for electric tramways in Genoa for £48,000. Part of the lines have been constructed and part are in course of construction.

Electrical Engineering in England.—Those who are desirous of perusing Mr. Kapp's paper on this subject, read before the recent meeting of the Union of German Electrical Engineers at Leipsic, will find an abstract of it in *L'Electricien* of July 7.

Electric Drills.—Herr Scheidl, one of the Austrian Governmental head mining managers, advocates, in the *Oesterreichische Zeitschrift für Berg und Hüttenwesen*, the use of electrically-operated drills in mining operations in preference to those operated hydraulically.

Electric Traction at Basle.—The municipal authorities have decided to construct an electric railway between the Central railway station and the Badische railway station. The estimated cost is £28,000, and the money will be supplied from the treasury of the canton.

Electric Lighting at Stuttgart. — The local authorities have purchased a site for a central electric light station. They have, however, decided not to run it on their own account, but to let the undertaking be carried out by Messrs. Schuckert and Co. of Nuremberg.

German Licensed Victuallers and Electricity. In August next there will be a meeting of the South German Licensed Victuallers at Darmstadt, in connection with which an exhibition will be held. The exhibits will include electrical appliances, lighting and signalling, and small motors.

Bordeaux International Exhibition.—The Department of Science and Art has received a despatch from her Majesty's Consul at Bordeaux calling attention to an international exhibition of arts, industries, etc., which it is proposed to hold in that city in 1895, under the patronage of the French Government.

Exhibition at Graz.—In September next there will be held at Graz an exhibition of machinery for small industries, and especially of machines driven by electric motors such as we have recorded as having taken place at Budapest. The Technological Trade Museum of Vienna will be one of the largest exhibitors.

Charing Cross-Hampstead Railway.—The Earl of Morley's committee have passed the Bill of the Charing Cross, Euston, and Hampstead Railway, which confers further powers upon the company and enables them to acquire additional lands, etc. The Bill was read a third time in the House of Lords on Monday and passed.

Telegraphy in South Africa.—The British South Africa Company state that the telegraph line to Buluwayo is to be completed by the end of this month. The company's line of telegraph is to be immediately extended from Buluwayo along the high veldt to a point between Charter and Victoria, where it will strike the line already laid.

Too Smart.—The *Daily Chronicle*, notwithstanding its seven or eight young men, is becoming almost as bad as the *Daily News*. One of its smart young sub-editors holds forth in a leaderette, scissored from *Industries and Iron*, concerning the schiesophone, an apparatus which it is declared will indicate flaws in iron and steel. Surely the *Daily Chronicle* remembers describing the same thing several years ago!

The Lowrie-Hall System.—The Leeds and London Electrical Engineering Company, Limited, of Hunslet, Leeds, and of 15, St. Helen's-place, E.C., have sent us a copy of their catalogue of electric lighting plant on the Lowrie-Hall system. This catalogue, which was referred to in the *Electrical Engineer* of September 1, 1893, has now been amplified by the addition of prices of some of the apparatus described in the list.

An Unnecessary Invention.—An American electrical contemporary, while objecting to electrocution, is desirous that some inventor should discover an electrical method of excruciating torture for Anarchists, such as the assassin of President Carnot. Surely what the Mikado described as "something lingering, with boiling oil or melted lead,' though old-fashioned, would serve the purpose quite well

Digitized by Google

without drawing electricians from more useful labours to find new methods.

Proposed Industrial Exhibition at Sunderland. Suggestions were made some time ago for the holding of a trades and industrial exhibition at Sunderland, and the scheme has been received with so much favour, and preparations are so much advanced, that it has been decided to open it in November. The prospectus explains that the undertaking will be an exposition of marine, manufacturing, electrical, engineering, and other industries.

"Invention" on Niagara.—That original (!) paper *Invention* says: "Prof. Forbes appears very sanguine about the success of the Niagara power scheme. . . . Applications for supply of power have been received from fully 350 miles distant: can this be wisely undertaken from a sound commercial aspect?" Fancy *Invention* endeavouring to set up as a critic! Our contemporary will soon begin telling us something about inventions and how to make fortunes out of them.

New Electrical Terminology. — Somebody in America has received an electric shock, and has sued for damages, when, if we are to believe a lay paper, the following evidence was tendered by experts: "'Ohm' is the term used to show the resistance; 'ampere' is the term used to describe a volt. A voltage of 1,500 would be styled an amperage of 10. A voltage of 6,000 would be required to propel an ampere three-quarters of an inch in length through a horse into a man under these conditions."

The Joule Studentship.—The president and council of the Royal Society have, upon the recommendation of the Joule Studentship Committee, elected Mr. J. D. Chorlton, B.Sc., of Owens College, Manchester, to the first Joule studentship. This studentship was founded for the purpose of enabling students to carry on certain researches on lines laid down by Dr. Joule, more especially with the view of determining the constants of some of the instruments employed by him, which his representatives can place at the student's disposal.

Electric Power Drill.—An electric auger drill for mining purposes has been brought out by the Jeffrey Manufacturing Company, of Columbus, U.S.A. It is capable of developing from 4 h.p. to 5 h.p. at the auger, though only half that is usually required. The motor is well protected by being enclosed in a steel casing on the sides, and by a steel plate on the side facing the coal or material to be drilled. The rear end of the motor is covered by a switchboard. Tests show that the efficiency of small sizes is 77 per cent., and of larger sizes 80 per cent.

The Giffard Prize for 1895.—The committee of French civil engineers selected to fix a subject for competition for next year's Giffard prize have fixed upon the following: "Transmission of power by means of electricity, either to machine tools in a workshop, or to the machinery of a railway or tramway line, or to the apparatus of a bridge, ship, dock, or public works." The competitor is to commence his paper by a summary of what has been done in the branch which he selects, following it by a description of work executed or a project capable of being carried out. The value of the prize next year will be £240.

Telephony in Germany.—Direct telephonic communication has been established between Berlin and Crefeld, a distance of about 240 miles. Two new telephone lines have been put into operation between Berlin and Friedrichshagen. A telephone line has been opened between Berlin and Heringsdorf, *vid* Stettin. During the present financial year Weimar and Jena will be connected telephonically, and both towns will be in communication with Wiemar, Erfurt, Gotha, Eisenach, Naumburg, Halle, Weissenfels, and Leipsic. Telephone exchanges have been established in connection with the telegraph offices at Adlig Liebenau and at Blonzmin.

Cable Stations.—In the House of Commons on Tuesday, Sir U. Kay-Shuttleworth, in reply to Sir G. Baden-Powell, said that soundings were taken by her Majesty's ship "Egeria" during a period of about two and a half years, from 1888 to 1890, between the North Cape of New Zealand and the Phœnix Islands, about 200 miles south of the equator; and the positions of several islands on that line were fixed and some were surveyed with a view to determining their suitability for cable stations. This was done in the ordinary course of hydrographic survey, in accordance with communications from the Admiralty to the Colonial Office. The distance between the extreme points of the area examined is over 2,000 miles.

A Marvellous Discovery.—Inventions which are prophesied to revolutionise something or other are more plentiful than blackberries, especially in America. The latest electrical revolutionary discovery is recorded by a San Francisco paper, which gives the following very lucid description: "In the ground generator, they simply insert zincs and carbon directly in the ground without any containing vessel or cell, and saturated with a very weak solution of acids. Then, when the power of the generator begins to run down, all that is required to restore full electro-force is to add another supply of the fluid. By this means the carbons are depolarised without removing them from the ground, consequently the generator can be run day and night until the zincs are worn out."

Telegraph Rates Between India and Europe.—We understand that the Indian Telegraph Department continues opening new offices, no fewer than 76 new combined offices having (according to the *Indian Engineer*) been opened since April last. The following extract from the recently published report of the council of the Society of Arts is of considerable interest in this connection: "On February 8, Mr. C. O. Walker read a paper on 'Telegraphic Communication Between England and India: its Present Condition and Future Development.' Speaking with a full knowledge of the subject, gained by long connection with the Indian Telegraph Department, Mr. Walker urged that a reduction of rates is both desirable and practicable, a view that would appear to be supported by all the Indian Chambers of Commerce."

The Photogene.—Our French contemporary *Electricité* describes in its issue of June 30 the photogene devised by M. Barruet. It states that the inventor, by the aid of his photogene and accessory clockwork mechanism, can charge successively, and without any interruption, the cells forming a battery of accumulators, which can at any time energise incandescent lamps and even one or two arc lamps. The photogene is a sulphate of copper battery which is automatically maintained. The E.M.F. of the photogene, which according to its size gives constantly from six to twelve amperes, is equal to one volt per cell. Several small installations on this system are said to have been in operation for two years, supplying lamps of from 5 c.p. to 16 c.p. of 24, 36, or 48 volts. The cost per kilowatt-hour is greater than that incidental to dynamos.

Institution of Mechanical Engineers.—The programme in connection with the forthcoming visit of the Institution of Mechanical Engineers to Manchester has been issued. Among the papers offered for reading and discussion at the meeting, which will be held in the Owens College, are the following: "Description of the New Electric Lighting Works, Manchester," by Dr. John Hop-

Digitized by Google

kinson, F.R.S., and "Electric Welding." by Mr. B. A. Dobson. The proceedings open with a reception of the council and members of the institution by the Lord Mayor of Manchester (Sir Anthony Marshall) and the Mayor of Salford (Sir William H. Bailey), at the Owens College, on Tuesday morning, the 31st inst., to be followed by the reading and discussion of papers on that and the subsequent Wednesday morning, the visit extending over until Friday.

Action Between Cable Companies.—The dispute between the Anglo-American and the French Paris and New York Telegraph Companies was decided by the High Court of Appeal in Paris on Tuesday. In 1886 the French Government protested against the treaty of 1880 between the two companies, and threatened to revoke the French company's concession. The latter accordingly denounced the treaty. The Anglo-American Company appealed to the French Courts, which gave judgment in its favour, but, on appeal, the question was referred to the Council of State to decide whether the French Company had acted under Government pressure. A fresh notification from the Government settled this point, and the Anglo-American Company consequently claimed damages for breach of contract. The Court on Tuesday held that damages were payable, and appointed three experts to appraise them.

A New Telephone System.—Señor R. Roderiguez Merino has devised a system of telephony in which the subscribers do not have batteries, and this has been laid by him before the Madrid Telegraph Department. He points out that the old system presents inconveniences, and that it would be better to have all the batteries at the exchange, where they could be easily controlled. Instead of sending the current from the battery through the microphone and the primary wire of an induction coil, while the telephone is connected with the secondary wire of this coil and the line, he connects the line conductors with the microphones and the primary wires of the induction coils, while the telephone is only connected with the secondary wire of the coil. The return takes place under the same conditions as before. The battery from which the microphone is worked can be placed at any part of the line, and it can therefore be placed in the exchange.

Telegraphy Between Australia and Canada.—It is reported that a proposal has been made by Mr. A. Siemens to the Government of the Dominion of Canada for laying a cable under the Pacific Ocean, from Victoria, British Columbia, to Sydney, New South Wales. He undertakes to complete the construction within three years. The offer is now being considered. According to the *Times* of yesterday, it appears that Mr. Siemens, who was unable to reach the Intercolonial Conference in time to present his views, issued a pamphlet to the delegates on Wednesday, giving his opinion as a cable expert that the existing surveys of the Pacific furnish an adequate basis for the immediate construction of a cable. He says that the technical obstacles which existed in 1887 to the laying of cables at uncertain depths have been removed by the test system now brought to perfection. His company would not hesitate to undertake the successful laying of the cable immediately, with an estimated total expenditure of £2,000,000.

Telephonic Extension in Yorkshire.—The National Telephone Company have at length completed the erection of their new trunk wire between Leeds and Scarborough. The work has been long in hand, the company having been greatly retarded by landowners and others. Owing to their opposition, it is said, the line, which is 73 miles in length, and has required 10 tons of copper wire, has had to be re-erected in part no less than three times, and the cost has been upwards of £10,000. Under such circumstances, it is stated that it cannot be expected to pay, but it was necessary in the development of the company's system, and, that being so, the enterprise has been prosecuted to the end. The new trunk wire was inaugurated on Monday, when at the Leeds end the Mayor (Mr. Leuty) took the principal part in the ceremony, whilst at the Scarborough end Alderman Champney took the place of the chief magistrate of that borough, who was prevented by family breavement from lending his aid on the occasion. Mr. Leuty switched on Scarborough at the Leeds exchange, and a conversation followed.

Hotel-Lighting.—A noteworthy feature of the Swiss hotels, and particularly those in the mountainous districts, is the fact that the watercourses frequently existing in the neighbourhood allow of the power being utilised in turbines for electric lighting purposes. One of the most recent instances in this direction is to be found at Ragaz, which is located in the Rhine valley, and in close proximity to the Tamin watercourse. There is an available fall of water of 50ft., and by using this it has been possible to obtain 480 h.p., which is employed for the lighting of the hotels and the principal local avenues. The plant laid down comprises three Girard turbines, having vertical shafts, and put down by MM. Rieter and Co. These turbines drive on to a common shaft from which the dynamos are operated by belting. The dynamos, of which there are four, are of the Oerlikon type, each of 72 kilowatts capacity, and giving 600 amperes at 120 volts when running at 420 revolutions a minute. The total number of lamps supplied comprises 2,000 incandescent and 42 arc lamps, whilst two lifts are actuated by electric motors.

Lighting of the Embankment.—The Highways Committee of the London County Council reported on Tuesday that they had considered the general description and specification of the engines, boilers, dynamos, and other machinery and plant which will be required for the generating station in connection with the electric lighting of the Victoria-embankment and Waterloo and Westminster Bridges, and that they had also had submitted to them an estimate of the cost. It appeared to the committee advisable that the supply of this machinery and plant should be the subject of two separate contracts, the one relating to the boilers and accessories, and the other to the engines, dynamos, etc.; and that having regard to the extreme importance of the electric light installation being completed and in operation before the end of the year, tenders should be invited without any avoidable delay. The committee therefore recommended that, subject to an estimate being submitted to the Council by the Finance Committee, tenders should be invited for the supply of the machinery and plant. This motion was carried, as was also a second proposal suggesting that designs should be obtained for the electric lamp standards to be erected on the Victoria-embankment. This matter has been referred to the Highways Committee to take the necessary measures for the purpose, and to advise the Council what premium should be offered for the best design.

Electric Light and Power Plant.—The preparation of a complete catalogue of electric lighting plant is not an easy matter, and that reason may be adduced for the non-appearance until the present of the catalogue of Messrs. Russell and Co., who some time ago opened offices at 11, Queen Victoria-street, E.C., and whose works are situated at Walham Green. Some idea of the extent of its size may be gathered from the fact that the catalogue covers 200 quarto pages. Boilers of various types first attract attention, these being followed by different kinds of steam-engines and combined boilers and engines for electric

Digitized by Google

lighting purposes, and gas and oil engines. In this connection a noteworthy feature may be cited in the case of a three-cylinder vertical type of oil-engine which has been designed for driving dynamos on board ship, and for other purposes where steady running and high speed are necessary. Then comes a list of dynamos for arc and incandescent lighting, together with some useful notes and data referring to the electrical transmission of power. Examples are given of the application of electric power in engineering works and factories, to cranes, capstans, and hoists, and for the operation of tramways. The practical utilisation of water power for electric lighting is demonstrated, as is also the use of electric search-lights. A large amount of space is also devoted to different types of measuring instruments, switches and switchboards, electric light fittings and accessories, telephones, etc. The catalogue will be useful both for the home and the export trade.

Tic Douloureux and Electricity.—In reference to a previous communication on this subject in the *Lancet*, Mr. Julius Althaus, M.D., of Harley-street, writes to that journal as follows: "The result of the use of the 'hydro-electric dipolar bath' in a severe case of trigeminal neuralgia certainly seems to have been magnificent in Dr. Hedley's hands, but the apparatus required for such a treatment is out of reach of most practitioners. It may therefore be useful to state that a much longer application of the continuous current, used in the ordinary way by moistened electrodes than was resorted to in the case alluded to, would probably have had the same effect. To apply the current in cases of severe tic douloureux for five minutes only, as was done by Dr. Hedley, can only be exceptionally useful. For a number of years past I have been in the habit of commencing the treatment in such cases with an application continued for at least 30 minutes, and have occasionally prolonged it for an hour. The result of a single such long application is generally most satisfactory, but the treatment has habitually to be continued daily for two or three weeks before the patient is thoroughly relieved. In order to avoid blistering the skin by such long applications it is advisable to use a very gentle force, say one milliampere. In one case, in which there was extreme sensitiveness to electricity, I have successfully used a current of 0·60 milliampere only. I generally apply the anode to the painful part, but in one most obstinate case I found it more effective to reverse the direction of the current in the metallic circuit every five minutes."

Country-House Electric Light Plant.—The popularity of electric lighting in country mansions and houses is increasing, and among those firms who have prominently taken up this branch may be mentioned Messrs. Drake and Gorham, who have just issued a revised illustrated catalogue of their specialities. The firm draw particular attention to the data given concerning the brake horse-power which can be economically and safely obtained from the different sizes of engines. This is generally a difficult thing to ascertain, and the figures contained in the cata logue are all the more valuable as having been obtained from the firm's actual practice in connection with semi-portable, vertical, and horizontal fixed steam-engines. Similar data are published relating to locomotive and Cornish boilers, the brake horse-power being obtained from the average results got in practice. Passing on from the dynamos, we note that there has been embodied in the "D. P." battery list some testimonials received by the firm. The object of the "Nevile" automatic accumulator switch, which is described in the catalogue, and for which the firm are sole agents, is to prevent the current from a battery of accumulators discharging itself through the dynamo when for any reason, such as a belt breaking, or the gas supply of a gas-engine being accidentally cut off, the E.M.F. of the dynamo falls below that of the battery. Then follow references to the firm's different types of switches for various purposes, and which are now well known. The remaining parts of the catalogue deal with the Cardew earthing device and voltmeter, ammeter, fuse-boxes, lamps, and estimates for electric lighting plant for installations of from 50 to 100 16-c.p. lamps. The catalogue—which, on the whole, deals with everything required in a complete installation—will prove of exceptional value to shippers and others.

Action of Electric Currents on Water-Pipes. At a recent meeting of the New England Waterworks Association, a paper on this subject was contributed by Messrs. Chas. A. Stone and Howard C. Forbes. So much attention has lately been given to electrolytic action that premature corrosion of water-pipes from any cause is likely to be attributed to electricity. Ordinary rusting does not take place at a uniform rate, varying, for instance, with the character of the soil, but often natural corrosion is hastened by the action of electric currents. The authors are now making experiments at the request of Mr. Wm. Jackson, M.Am.Soc.C.E., city engineer of Boston, to find a method of distinguishing between electrolytic and natural corrosion. The various methods proposed to prevent electrolysis may be classed under three heads, as follows: (1) complete remedies, such as the double trolley and storage battery systems, complete insulation of the pipes and possibly the alternating system. For the present, the first three systems are considered as in themselves impracticable, and it is yet too early to pronounce upon the latter. (2) Partial remedies, such as very heavy return wires from the tracks to the power station, with good bonds between the rails; also returns from sections of track every 500ft. along the route; but this can never entirely do away with the difficulty; the three-wire system, regarding which little is actually known and which is not as yet promising; insulation of tracks, which, as indicated, only tends to reduce the injury. (3) Schemes which are useless, as connections from the tracks to the pipes, bringing the pipes to uniform potential and reversing the current at frequent intervals. In addition to the above methods, the connection of the pipes to the negative plate at the power station has been tried several times, and with beneficial results. The problem here is to get the current through the joints in the pipe without injuring the latter.

The Pacific Cable Question.—In the course of an editorial on the Ottawa Conference, and to which we referred last week, the *Times* says: "The immediate practical question which was submitted to the delegates was the motion approving the construction of a Pacific cable, directly connecting Canada and the Australian colonies and free from foreign control. That this plan will be ultimately carried into effect and extended, as the colonies concerned demand, by subsidiary links with New Zealand on the one hand and South Africa on the other, can hardly be doubted. But the delegates have shown their common sense by declining to commit themselves to a comprehensive and, perhaps, a very costly scheme until the facts of the case are fully before them. The data before the conference were regarded as insufficient to justify a vote for the immediate construction of the Pacific cable, and last week a motion to that effect was accordingly rejected. It was resolved to recommend a careful and exhaustive survey, the cost of which, estimated not to exceed £25,000, should be borne partly by Canada and the Australasian colonies and partly by the Imperial Government. We can

Digitized by Google

see no objection whatever to this proposal, and we cannot doubt that if the results of the survey are satisfactory, the work will meet with approval both here and in the colonies. In the present stage of the question, however, the colonists are quite right to hold their hands. The opposition which the project of a Pacific telegraph cable connecting Canada directly with Australia has met with in this country is quite natural. A practical monopoly of a large and lucrative business cannot be expected to welcome competition. We fully recognise the advantages which the existing telegraph companies connecting England with the East and with Australasia have secured for business men, but we do not think it has been shown that their routes would be as safe in time of war as a Pacific line entirely under British control. The subject, however, is for the present relegated to the region of enquiry and experiment." The Inter-Colonial Conference on Monday passed a resolution asking the Canadian Government, after the rising of the conference, to make all necessary enquiries and generally to take steps expedient to ascertain the cost of a Pacific cable, and promote the establishment of the undertaking in accordance with the views expressed by the conference.

The Cance Rheostat. — In a recent issue of *L'Electricien* an illustrated description is given by "A. M." of the Cance rheostat. The apparatus, which is of the fixed drum type, consists of a vertical tube of cylindrical form made of enamelled iron, on which is wound a wire of ferro-nickel, and of increasing section. This tube is bolted to a base-plate by means of three bolts, which also keep in position a slate plate, the object of which is to insulate the lower part of the tube. A vertical shaft turning in a socket fixed on the base-plate is contained inside the tube, a bronze disc maintaining the upper part of the shaft in position. This shaft has arranged on it an iron wheel, which supports three vertical copper rods, connected together at their lower ends by means of a copper crown. The latter is supported by rollers, when the apparatus is revolved by means of a handle. Two copper crowns can move along the vertical rods, with which electrical connection is maintained constantly by the aid of brushes. These two crowns serve as support to three rollers, the axes of which are placed vertically; suitable springs cause them to press continually on the wire wound on the cylindrical tube. A single roller would have been sufficient to ensure the collection of current, but M. Cance has found that three rollers assured a concentric guide in the rotation of this part of the apparatus, and gave at the same time an electrical contact as perfect as possible. The current is obtained from two terminals arranged on the base-plate. One of these is connected to the upper end of the ferro-nickel resistance, whilst the other is united to a brush, which presses upon the central shaft conjointly with the iron wheel, and consequently with the three copper rods and the three rollers carried by the two crowns. As the enamelled iron cylinder is insulated, the current arriving by one terminal enters through the upper part of the wire, follows it until it meets the rollers, and returns to the other terminal by the intermediary of the two crowns, the three copper rods, the wheel and the central shaft. The working of this rheostat, our contemporary states, is easy of comprehension. The rollers are constantly pressing on the wire forming the fixed resistance, and they are at the same time conjointly liable with the two crowns, which can only ascend or descend along the copper rods by turning with them. These rollers constitute then a kind of single-threaded screw screwing itself up or down the ferro-nickel winding. "A. M." states that with this type of rheostat it is very easy to insert in the circuit any desired resistance with great precision, both in the case of very weak or very strong variations.

The Wiring of Ships.—A short article on the wiring of ships, by M. M. Leroy, appears in *L'Electricien* of the 7th inst. The author states that there are no Government vessels in France where the return is formed by the mass of the vessel, but that some companies, and particularly the steamers of the Compagnie des Messageries Maritimes, use the hull as the return. M. Leroy considers that the latter method possesses such considerable advantages, from the point of view of economy and simplicity, as to appear to be the only practical system. The circuits from the dynamo to the lamps are carefully insulated, and the leading-out wire from each lamp and the second pole of the dynamo are placed in connection with the hull. Suitable cut-outs being placed at each branch conductor, the author states that accidents arising from any contacts established between the insulated cable and the hull will simply melt the branch fuse, and the fault will thus be localised. Moreover, the economy realised by the laying of conductors on this system allows of the choice of the best quality of insulated conductor, thus rendering accidents less frequent. In practice the only circuits which are found in the worst condition are those which traverse the holds of vessels, which are always damp either through the condensation which is produced on the internal walls or through the percolation of sea-water due to the washing of the bridges. The circuits from which the head lights and bridge lights are energised are also exposed to the action of sea-water. Whether the circuits are double or single wiring, M. Leroy believes from this point of view that the effects of the water are equally disastrous. Slow electrolysis, the formation of salts on the conductor, and the destruction of the insulating material will, he says, inevitably be produced. The only resource available lies in the quality and thickness of the insulation. As it is more economical to have a single conductor having an insulation superior to that of two wires, he considers that in such a case the advantage of a double circuit is illusory. The author says that some persons have attributed to lighting circuits with a single wire the deviation of the compass, which is generally itself lighted by a lamp placed underneath it. This action, he continues, is absolutely nil, unless, owing to negligence, a circuit of great intensity is carried at the side of it. The iron masses surrounding closely the compass constitute a magnetic screen, which protects it against the effects of the currents. It would, moreover, be possible to wrongly affect the compass indications with a double-wire circuit, if the latter wires, as is frequently the case, are not side by side. When, however, the circuits supply both incandescent lamps and projectors, M. Leroy is not of the same opinion. In fact, the currents traversing these conductors are, on the one hand, powerful, being from 70 to 80 amperes per projector; on the other hand, the external position of the projectors renders them liable to be often wet by the salt water. The cables which convey the current to the projectors must allow of displacement in every direction, and they are therefore supple, and consequently badly insulated. These circuits should be kept distinct from others, and the author states that M. Leblond goes so far as to state that a dynamo should be laid down for each search-light. The author concludes that circuits should be insulated throughout on war vessels, where the question of economy disappears before that of security. On steamers, however, M. Leroy says that he is in favour of single wiring, notwithstanding the campaign organised against this method recently in England.

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 7.)

§ 32. The units hitherto discussed, the symbols used for them, and the dimensional expressions obtained for them, may be put into a tabular form.

Name.	Symbol.	Dimensions in L M T.
Plane angle	θ	—
Solid angle	Ω	—
Strain	—	—
Specific gravity	—	—
Curvature	$1/\zeta$	L^{-1}
Tortuosity	$1/\zeta^1$	L^{-1}
Area	S	L^2
Volume	V	L^3
Linear velocity	v, $\dot{L}$	$L\,T^{-1}$
Angular velocity	ω, $\dot{\theta}$	T^{-1}
Linear acceleration	α, $\dot{v}$, $\ddot{L}$	$L\,T^{-2}$
Angular acceleration	ω, $\ddot{\theta}$	T^{-2}
Moment of inertia	I	$L^2\,M$
Density	D	$L^{-3}\,M$
Momentum	$M\,v$	$L\,M\,T^{-1}$
Impulse	$F\,t$	
Force	F	$L\,M\,T^{-2}$
Moment of momentum	$I\,\omega$ / $G\,t$	$L^2\,M\,T^{-1}$
Torque	G	$L^2\,M\,T^{-2}$
Work / Energy	W $F.s$ / $G.\theta$; E $\frac{1}{2}M\,v^2$ / $\frac{1}{2}I\,\omega^2$	$L^2\,M\,T^{-2}$
Energy per unit area	—	$M\,T^{-2}$
Energy per unit volume	—	$L^{-1}\,M\,T^{-2}$
Activity	A	$L^2\,M\,T^{-3}$
Stress / Pressure	P	$L^{-1}\,M\,T^{-2}$
Surface tension	τ	$M\,T^{-2}$
Rigidity modulus	n	$L^{-1}\,M\,T^{-2}$
Bulk modulus	k	
Young's modulus	M	
Torsional rigidity	N	$L^3\,M\,T^{-2}$
Flexural rigidity	N^1	
Viscosity	μ	$L^{-1}\,M\,T^{-1}$
Diffusivity	κ	$L^2\,T^{-1}$

§ 33. These dimensional formulæ may be used: (1) to find the change that takes place in any derived unit when the fundamental unit is altered; (2) to check any result we may have arrived at in an investigation by counting the dimensions; and to a limited extent, (3) to anticipate results of a dynamical investigation by reasoning based on dimensions. Examples are appended to illustrate these statements. W. Williams, in a paper entitled "On the Relation of the Dimensions of Physical Quantities to Direction in Space," printed in the *Proceedings* of the Physical Society, vol. xi., 1890-92, uses three rectangular directions, X, Y, Z, and hence shows that "the dimensional formulæ may be taken as representing the *physical identities* of the various quantities, as indicating, in fact, how our conceptions of their physical nature (in terms, of course, of other and more fundamental conceptions) are formed—just as the formula of a chemical compound indicates its composition and chemical identity."

§ 34. How many ergs are there in a foot-pound?

The dimensional formula for work is $[L^2\,M\,T^{-2}]$. Let x be the number of ergs corresponding to 32·2 foot-poundals, then

$$x\,\frac{(1\text{ft.})^2\times 1\text{lb.}}{(1\text{ sec.})^2} = 32{\cdot}2\,\frac{(30{\cdot}48)^2\times 453{\cdot}6}{1^2};$$

$$\therefore x = 13{\cdot}56\times 10^6 \text{ ergs},$$

or, 1 foot-pound = 30·48 cm.-lb.;

$$= 30{\cdot}48\times 453{\cdot}6 \text{ cm.-gm.};$$

$$= 30{\cdot}48\times 453{\cdot}6\times 981 \text{ cm.-dynes};$$

$$= 13{\cdot}56\times 10^6 \text{ ergs}.$$

2. Determine the unit of time in order that, the foot being the unit of length, g may be expressed by unity.

The dimensional formula for acceleration is $[L\,T^{-2}]$.

Therefore, $32\times\frac{\text{ft.}}{(\text{sec.})^2} = \frac{\text{ft.}}{t^2}$

$$\therefore t^2 = \frac{1}{32}$$

$$t = \frac{1}{4\sqrt{2}} \text{ second.}$$

$$= \tfrac{1}{8}\sqrt{2} = \cdot 177 \text{ second.}$$

3. If the acceleration due to gravity be taken as the unit acceleration, and the velocity generated in one minute as the unit of velocity, find the unit of length—38,400 yards.

The velocity acquired by a falling body in one minute is $32\times 60 = 1{,}920$ft. per second.

Hence
$$32\times\frac{\text{ft.}}{(\text{sec.})^2} = \frac{l}{t^2} \quad \ldots\ldots (1)$$

$$1{,}920\times\frac{\text{ft.}}{(\text{sec.})} = \frac{l}{t} \quad \ldots\ldots (2)$$

$$\therefore t = \frac{l}{1{,}920}.$$

Substituting in (1) $l = 32\,t^2 = \frac{32\,l^2}{(1{,}920)^2}$;

$$\therefore l = \frac{(1{,}920)^2}{32} = 60\times 1{,}920 \text{ feet};$$

$$= 38{,}400 \text{ yards};$$

$$= 21\tfrac{9}{11} \text{ miles}.$$

4. A body moving uniformly passes over a mile in 15 minutes. If 64 be the measure of velocity, and 11ft. the unit of length, find the unit of time.

A mile in 15 minutes $= \frac{88}{15}$ft. per second.

$$\tfrac{88}{15}\cdot\frac{1\text{ft.}}{1\text{sec.}} = 64\,\frac{11}{t};$$

$$\therefore t = \frac{64\times 11\times 15}{88} = 120 \text{ secs.} = 2 \text{ minutes}.$$

5. If the force of gravity be taken as the unit of force, and a rate of 10 miles an hour as the unit of velocity, what must be the units of time and length?

The dimensions for force and velocity are $[L\,M\,T^{-2}]$ and $[L\,T^{-1}]$ and 10 miles an hour $= \frac{44}{3}$ft. per second.

Hence
$$32\times\frac{\text{ft.}}{(\text{sec.})^2} = \frac{l}{t^2} \quad \ldots\ldots (1)$$

and
$$\tfrac{44}{3}\times\frac{\text{ft.}}{(\text{sec.})} = \frac{l}{t} \quad \ldots\ldots (2)$$

where l and t are the required units of length and time.

From (2) $l = \frac{44}{3}\,t$, and substituting in

(1) $t = \frac{44}{3}\times\frac{1}{32} = \frac{11}{24}$ second.

Therefore $l = \frac{121}{18}$ft.

This is equivalent to saying that a falling body acquires a velocity of $\frac{121}{18}$ft. per $\frac{11}{24}$ second at the end of $\frac{11}{24}$ second of its fall, or 32ft. per second per second $= \frac{121}{18}$ft. per $\frac{11}{24}$ second per $\frac{11}{24}$ second.

6. A shot weighing a lbs. is fired from a gun with a velocity of v ft. per second. If its kinetic energy, the impulse it has received, and the acceleration due to gravity be denoted by k, i, and f respectively, find the units of length, mass, and time.

$$\tfrac{1}{2}\,a\,v^2\,\frac{(1\text{ft.})^2\,(1\text{lb.})}{(1\text{sec.})^2} = k\,\frac{l^2\,m}{t^2} \quad \ldots (1)$$

$$a\,v\,\frac{(1\text{ft.})\,(1\text{lb.})}{(1\text{sec.})} = i\,\frac{l\,m}{t} \quad \ldots (2)$$

Digitized by Google

$$g\frac{(1\text{ft.})}{(1\text{sec.})^2} = f\frac{l}{t^2} \quad . \quad . \quad . \quad (3)$$

From (1) and (2) $m = \frac{a v^2 t^2}{2 k l^2} = \frac{a v t}{i l}$;

$$\therefore \frac{l}{t} = \frac{v i}{2 k} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and from (3) $\frac{l}{t} = \frac{g t}{f}$;

$$\therefore \frac{g t}{f} = \frac{v i}{2 k} \text{ and } t = \frac{v i f}{2 k g}.$$

From (4) $l = \frac{v i}{2 k} \times t = \frac{v^2 i^2 f}{4 g k^2}$.

Hence $$m = \frac{a v}{i} \times \frac{t}{l} = \frac{2 a k}{i^2}.$$

For example, if $a = 2$oz., $v = 800$ft. per second, and $k = i = f =$ unity, then $t = \frac{v}{2g} = 15$secs., $l = \frac{v^2}{4g} = 5{,}000$ft., and $m = 2a = \frac{1}{4}$lb.

§ 35. 1. A person deduces from some investigations the following equations. Determine whether they are possible or not.

$$(a)\ 6\,M^2\,V + 2\,g^3\,F\,L^2\,D\,T^8 - 3\,F^2\,L\,T^4 = 0;$$

$$(b)\ v^3\,T - 4\,M\,a\,L + 3\,F = 0.$$

Substituting the dimensional expressions for each of the terms in equation (a) we get

$$M^2\,L^3, \left(\frac{L}{T^2}\right)^3 \times \frac{L\,M}{T^2} \times L^2 \times \frac{M}{L^3} \times T^8, \left(\frac{L\,M}{T^2}\right)^2 \times L \times T^4,$$

which reduces to

$$L^3\,M^2,\ L^3\,M^2,\ L^3\,M^2.$$

The three terms are of the same dimensions, therefore the equation is possible.

Substituting dimensions in equation (b) we get

$$\left(\frac{L}{T}\right)^3 T, M \times \frac{L}{T^2} \times L, \frac{M\,L}{T^2},$$

which reduces to

$$\frac{L^3}{T^2}, M\frac{L^2}{T^2}, \frac{M\,L}{T^2}.$$

The three terms are not of the same dimensions, and therefore the equation is physically impossible.

§ 36. 1. The centrifugal force acting on a body depends on the mass of the body, the velocity of the body, and the radius of the circle the body is describing.

Let the index of each of these be x, y, z, then $F = m^x \cdot v^y \cdot r^z$.

Substituting dimensions

$$L\,M\,T^{-2} = M^x \times (L\,T^{-1})^y \times L^z;$$
$$= M^x \times L^{y+z} \times T^{-y}.$$

Equating coefficients of L, M, T, we get

$$1 = y + z;\ 1 = x;\ -2 = -y.$$
$$\therefore x = 1;\ y = 2;\ z = -1.$$
$$\therefore F = m \cdot v^2 \cdot r^{-1} = \frac{m v^2}{r}.$$

2. The velocity of a distortional wave through a material depends on the rigidity modulus of the material and on its density. Let us suppose that it varies as the xth power of n and as the yth power of D.

Then $$v = n^x \cdot D^y;$$
$$L\,T^{-1} = (L^{-1}\,M\,T^{-2})^x \times (L^{-3}\,M)^y.$$

Equating the indices of L, M, t:

$$1 = -x - 3y;$$
$$0 = x + y;$$
$$-1 = -2x. \quad \therefore x = \tfrac{1}{2}, \text{ and } y = -\tfrac{1}{2}.$$
$$\therefore v = \sqrt{\frac{n}{D}}.$$

If the modulus be expressed in gravitation units this could be written $v = \sqrt{\frac{g\,n}{D}} = \sqrt{g\,L}$, where L is the length modulus of rigidity. Generally the corresponding length modulus is the modulus in gravitation measure divided by the density. Hence we can say that the velocity of any wave-motion through any material is the velocity a body would acquire in falling through a height equal to half the proper length modulus.* The proper length moduluses for the following wave-motions are:

1. Longitudinal vibrations along a bar or cord, $L = M/D$.
2. Waves of simple distortion, $L = n/D$.
3. Waves along a bar or cord which is prevented from lateral shrinking, or waves of simple longitudinal extension and contraction in a homogeneous isotropic infinite solid—that is, waves analogous to sound, $L = \left(k + \frac{4n}{3}\right)/D$.
4. Sound-waves in a fluid, $L = k/D$.
5. Sound-waves in air, $L = k/D$, or $P/D =$ height of the homogeneous atmosphere.
6. Long waves in water of uniform depth, L = depth.
7. Deep-water waves, L ÷ wave-length/2π.
8. Transverse pulse in stretched cord, L = length of cord amounting in weight to the stretching weight = W/m, where W is the stretching weight, and m the mass of the cord per unit length.

(To be continued.)

AN AUTOMATIC VARIABLE STEAM CUT-OFF OPERATED BY ELECTRICITY.

Acting on the supposition that mechanical contrivances for varying the point of cut-off in steam admission to an

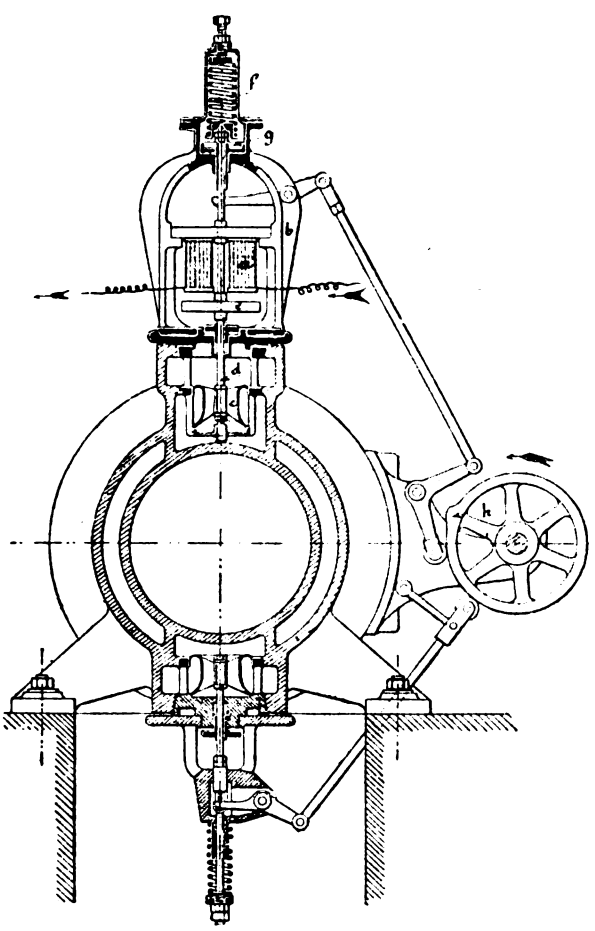

FIG. 1.

engine cylinder are usually required to be extremely sensitive and quick in their result, a French engineer named Décombe has devised, says *La Revue Industrielle*, an electrical appliance by means of which the steam admission is

* See Lord Kelvin's "Mathematical and Physical Papers," vol. iii., § xcii., p. 40, and § civ. p. 519.

Digitized by Google

automatically regulated in accordance with the load. This device is illustrated in the annexed engravings, which represent it as applied to a horizontal engine of the Sulzer type. The idea is, of course, that the appliance will be specially suited for the electricity supply stations, where it is not only important that the engine speed shall be maintained as constant as possible, but where there is also a supply of electric energy at once available for operating the contrivance without the necessity of special apparatus for giving an electric current.

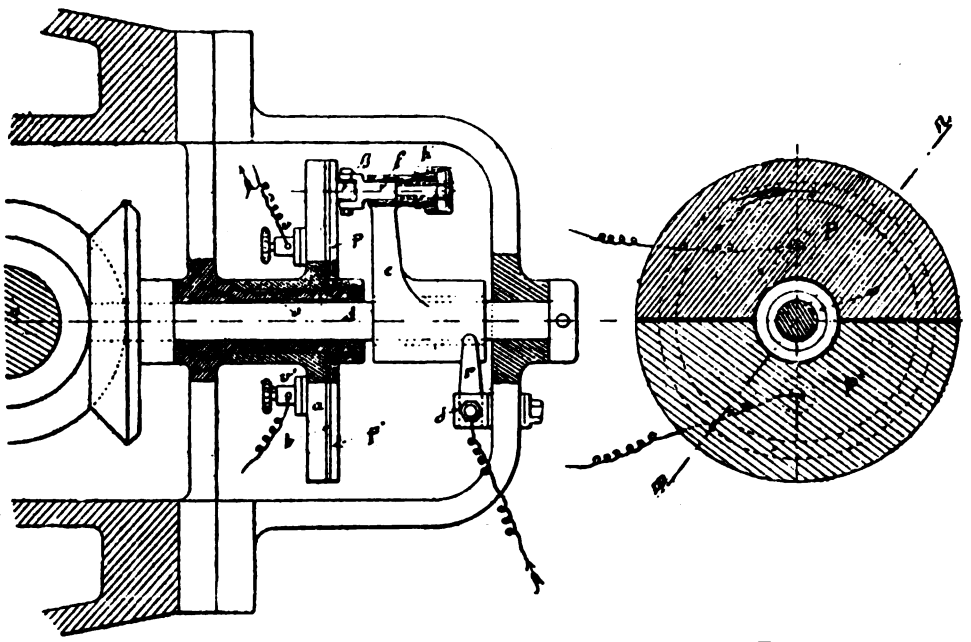

FIG. 2.

FIG. 3.

In this device the actual opening of the steam-valve is effected in the usual manner by a rocking shaft and bell lever, and the lifting impulse is given by means of a cam or projection upon the circumference of a wheel shown in Fig. 1, at *h*. This raises the valve, *c*, and valve stem, *d*; on the latter is fixed an armature, *e*, which comes into contact with the poles of an electromagnet, *a*. The coils of this magnet are energised in a way shortly to be described, for a length of time varying inversely with the engine speed—that is, the magnet retains the armature and with it the valve in a raised position, exactly according to the position of the engine governor. When current ceases to pass through the coils, the armature, with the valve, is caused to drop by the action of a coiled spring shown at *f*, provided with a dashpot, *g*, to prevent too sudden a descent of the valve upon its seat.

The magnet thus employed to determine the point of cut-off receives current from any suitable source through a commutator, which is shown sectionally in Fig. 2. This commutator is formed of two semi-circular, thin, flat plates, P and P^1, of brass, mounted on a disc, *b*, of ebonite and insulated from one another. The entire arrangement is fixed to a face-plate, *a*, which is capable of a slight angular motion upon the sleeve, *s*, cast in one piece with the adjacent supporting bracket. In this position it is subjected directly to the action of the governor, moving round in one way or another according as the governor rises or falls.

Through the sleeve, *s*, passes a small spindle, *d*, rotated by bevel gear from the engine crankshaft. It carries on the outer end an insulated crankpiece, *e*, with a rolling contact wheel, *g*: this latter is forced outwards by the spring, *h*, against the metal plates already alluded to, which are shown in front view in Fig. 3. At *i* is a small screw adjustment to regulate the pressure of contact. Another contact—by means of a spring or brush—at *r* serves to put the wheel and plates into connection with the source of electricity; and two insulated terminals, *v*, *v*^{1}, lead the current from the respective plates to each end of the engine cylinder, as shown in Fig. 4.

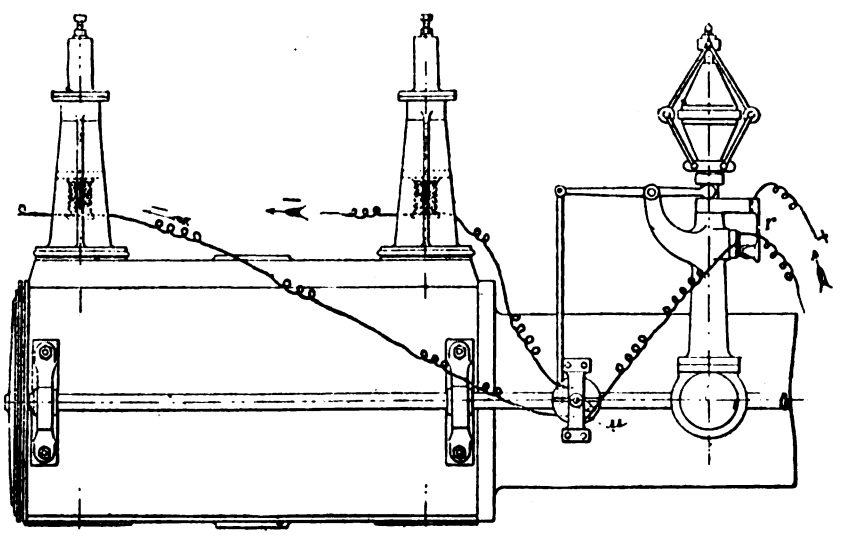

FIG. 4.

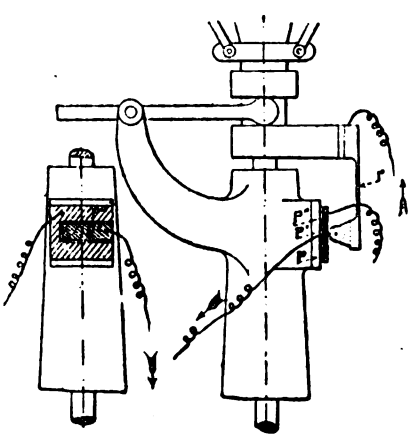

FIG. 5.

FIG. 6.

Since the point of admission is constant, owing to the use of a mechanical device of cam and lever for opening the valve, it may be defined as lying on a straight line, *m n* (Fig. 3). The two dotted rings in this illustration represent the path of the small contact wheel, *g*; as soon as this arrives at the line, *m n*, the valve is opened at one or other end of the cylinder, according as the wheel is on plate P or P^1. The cut-off takes place as soon as the wheel touches the insulation between the plates.

It depends, therefore, upon the angular position of the face-plate, *a*, in respect to the line *m n*; and, as already

Digitized by Google

stated, this may be varied to a slight extent (sufficient for the purpose) by a lever connected with the governor, as shown in Fig. 4, where the crank and disc are referred to by the letter *u*.

In the same illustration may be noted the arrangement for automatically stopping the engine when its speed (and therefore that of the governor also) rises above a proper limit. At *r* is fixed a spring contact with rubbing wheel—shown in greater detail in Figs. 5 and 6—by means of which the current actuating the regulating magnets just described is caused to pass through the middle contact-plate, P^1, to the crank arm and disc, *u*, or else passes through the U-shaped plate above and below P^1 to another electromagnet, which releases a detent and by counter-weights closes the steam-admission valve.

PRACTICAL NOTES ON DYNAMO CALCULATION.–V.*

BY ALFRED E. WIENER.

13. *Total Length of Armature Conductor.*—The amount of inactive or "dead" wire required to join the active portions of the armature conductors into continuous turns depends upon the shape of the armature, the height of the winding space, and the manner of winding. In an armature, for instance, having a core section of great length of parallel to the pole faces, and but a small thickness perpendicular to the same, this useless addition to the generating wire will be comparatively small, while in short armatures with great core depth the proportion of the dead to the active length will be considerably greater. Furthermore, if two armatures of same length, same core diameter, and same radial depth, have equal lengths of active conductor, but are wound with different heights of the winding space—as well be the case if the one has a smooth core with winding covering the entire circumference and the other a toothed body—then the external diameters, and consequently the lengths necessary to join the active conductors, are greater in the latter case, and therefore it is evident that the armature with the higher winding space requires a greater total length of armature conductor. If, finally, two otherwise entirely equivalent armatures are wound by different systems, a considerable difference may be found in the total lengths of wire required to produce equal lengths of active conductor.

(*a*) *Drum Armatures.*—The active length of the armature conductor being known, the simplest method of expressing its total length, for a drum armature, is

$$L_t = k_3 \times L_a \quad . \quad . \quad . \quad . \quad . \quad (19)$$

where L_t = total length of armature conductor, in feet (parallel wires considered as one conductor);
L_a = active length of armature conductor, in feet, from formula (3);
k_3 = constant, depending upon shape of armature and system of winding (see Table XIX.).

The ratio, k_3, of the total to the active length of the armature conductor in a drum armature depends chiefly upon the ratio of length to diameter of the armature core. In modern machines the lengths of drum armatures usually vary between one and two diameters; in special designs, however, a value as low as 0·75 or as high as 2·5 may be taken for this ratio. Table XIX. gives average values of the constant k_3 for various shape-ratios, for smooth as well as for toothed drum armatures.

Another form often used for expressing the total length of wire on a drum armature is indicated by the formula:

$$L_t = K \times (l_a + k_4 \times d_a) = L_a \times \left(1 + k_4 \times \frac{d_a}{l_a}\right). \quad (20)$$

K = total number of conductors all around armature circumference;
k_4 = constant depending upon system of winding.

This formula (20) has the advantage over (19) that no special table is required for its constant, since for a certain type of armature, and a certain system of winding, k_4 is very nearly constant for all sizes and shapes. The value of k_4 for the smooth drum armatures considered in Table XIX.

* From the *Electrical World* (New York).

TABLE XIX.—Ratio between Total and Active Length of Wire on Drum Armatures.

Ratio of length to diameter of armature core. $l_a : d_a$	Value of k_3. Smooth armature.	Toothed armature.
0·75	2·50	3·10
0·8	2·45	3·05
0·9	2·40	3·00
1	2·35	2·95
1·1	2·30	2·90
1·2	2·25	2·85
1·3	2·20	2·80
1·4	2·15	2·75
1·5	2·10	2·70
1·6	2·05	2·65
1·7	2	2·60
1·8	1·95	2·55
1·9	1·90	2·50
2	1·85	2·45
2·25	1·75	2·35
2·5	1·70	2·25

lies between 1·3 and 1·7, and as an average 1·5 may be taken, thus making the formula for the total length of conductor for smooth drum armatures:

$$L_t = L_a \times \left(1 + 1{\cdot}5 \times \frac{d_a}{l_a}\right). \quad . \quad . \quad (21)$$

Formula (21), then, means that the additional length of dead wire to every conductor of a smooth drum armature is one and one half times its core diameter, or that the total length of one conductor in a smooth drum is equal to the length of the body plus one and a half times the core diameter. The reason why k_4, even for the same type and same winding method, has not the same value for all sizes, is that the proportion of the core diameter to the thickness of the armature shaft is very much different for different sizes. In a small drum, for instance, the shaft takes up considerably much more room than in a large one, and, therefore the dead lengths are comparatively larger in a small machine. In fact, $k_4 = 1{\cdot}5$ gives too high values for small ratios of length to diameter, which occur in large drums, while the values found by (21) for large ratios of length to diameter, which are met in small armatures, are below those given in Table XIX.

For $l_a : d_a = 1$, or $d_a : l_a = 1$, for instance, we obtain, by comparison of (19) with (20) and (21):

$$k_3 = \frac{L_t}{L_a} = 1 + k_4 \times \frac{d_a}{l_a} = 1 + 1{\cdot}5 \times 1 = 2{\cdot}5,$$

while Table XIX., which is averaged from actual practice, gives $k_3 = 1{\cdot}35$ for this ratio, to which number would correspond the small value of $k_4 = 1{\cdot}35$.

On the other hand, if $l_a : d_a = 2$, or $d_a : l_a = 0{\cdot}5$, we get:

$$k_3 = 1 + 1{\cdot}5 \times 0{\cdot}5 = 1{\cdot}75;$$

the table-value for k_3 is 1·85 for this shape-ratio, and therefore the high value of $k_4 = 1{\cdot}70$ would answer in this case.

For toothed drum armatures the numerical value of k_4, in the practical limits of the ratio of shape, lies between 1·9 and 3, the average being about 2·5; hence formula (20) for toothed drum armatures becomes:

$$L_t = L_a \times \left(1 + 2{\cdot}5 \times \frac{d_a}{l_a}\right) \quad . \quad . \quad . \quad (22)$$

that is to say, the average length to be added to each active conductor in a toothed drum armature is $2\frac{1}{2}$ times the core diameter of the drum, or the average dead length in each turn (consisting of two active conductors) is five times the diameter at the bottom of the slots.

(*b*) *Ring Armatures.*—In a Gramme-wound ring armature of a core section of given dimensions, the ratio of the total to the active length of the conductor depends upon the arrangement of the field-magnet frame. There are, altogether, eight different possibilities of arranging the poles around a ring armature; these eight methods, however, can be classified into but five principally different cases—viz.:

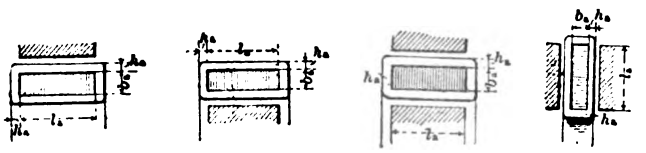
Case I. Pole-pieces facing *one* long armature surface, see Figs. 4 and 5;
Case II. " " *two* long armature surfaces, see Figs. 6 and 7;

Digitized by Google

Case III. Pole-pieces facing *one* long and *two* short armature surfaces, see Fig. 8;

Case IV. „ „ two long and one short armature surface, see Figs. 9 and 10;

Case V. „ „ one long, two short, and part of second long surface, see Fig. 11.



FIGS. 4, 5, 6, AND 7.

Denoting with l_a the length, and with b_a the breadth of the cross-section, and assuming the winding height, h_a, to be the same all around the section, we obtain the following formulæ for calculating the total length of conductor on a ring armature:

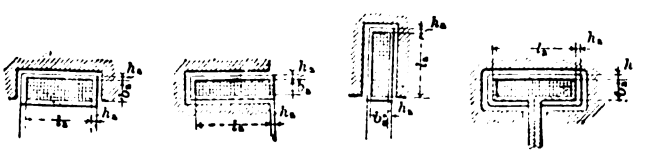
$$\text{Case I}: L_t = \frac{2 \times (l_a + b_a + h_a)}{l_a} \times L_a \quad . \quad . \quad . \quad (23)$$

$$\text{„ II.}: L_t = \frac{l_a + b_a + h_a}{l_a} \times L_a \quad . \quad . \quad . \quad . \quad (24)$$

$$\text{„ III.}: L_t = \frac{2 \times (l_a + b_a + h_a)}{l_a + 2\,b_a + h_a} \times L_a \quad . \quad . \quad . \quad (25)$$

$$\text{„ IV.}: L_t = \frac{2 \times (l_a + b_a + h_a)}{2\,l_a + b_a + h_a} \times L_a \quad . \quad . \quad . \quad (26)$$

In these formulæ l_a, b_a, and L_a are known by virtue of equations (12), (18), and (3) respectively, and h_a can be taken from Table XV., if the actual winding depth is not already known by having previously determined the winding and its arrangement.



FIGS. 8, 9, 10, AND 11.

A formula for Case V. is not given, because, in the first place, the arrangement shown in Fig. 11 is not at all practical, and the makers who first introduced the same have long since discarded it, and second, because the distance of the internal pole projecting depends upon the construction and manner of supporting of the armature core, and consequently cannot be definitely expressed.

(c) Drum-Wound Ring Armatures.—In modern ring armatures of the types indicated by Figs. 4 and 5, the conductors facing two adjacent poles of opposite polarity are often connected in the fashion of a bipolar drum, by completing their turns across the end surfaces of the armature body, thus converting the multipolar ring armature into the combination of as many bipolar drum armatures as there are pairs of poles in the field frame (see Chapter 25).

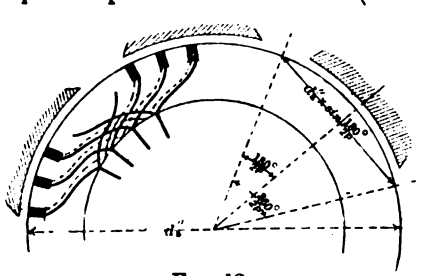


FIG. 12.

By this arrangement, which is illustrated in Fig. 12, not only a considerable saving of dead wire is experienced, but also the exchanging of conductors in case of repair is rendered much more convenient, especially when in bending of the connection strips the Eickemeyer method is applied.

The total length of the armature conductor can in this case be calculated by applying for both smooth and toothed bodies the above formula (21), replacing in the same the core diameter, d_a, by the chordal distance of two neighbouring poles, measured from centre to centre along the circumference of the armature over the winding. The formula for the total length of conductor on a drum-wound ring armature, therefore, is (see Fig. 12):

$$L_t = \left(1 + 1{\cdot}5 \times \frac{d_a'' \times \sin \frac{180\text{deg.}}{2\,P}}{l_a}\right) \times L_a. \quad (27)$$

Inserting in this formula the numerical value for the size of half the pole angle, we obtain the following set of formulæ for the various pole numbers that may be used in practice:

TABLE XX.—Total Length of Conductor on Drum-wound Ring Armatures.

Number of poles. 2 P.	Half pole-angle. $\frac{180°}{2\,P}$	Length of pole-chord (Diameter = 1) $\sin \frac{180°}{2\,P}$.	Total length of armature conductor (formula 27) $L_t = \left\{1 + \left(1{\cdot}5 \times \sin\frac{180}{2\,P}\right) \times \frac{d_a''}{l_a}\right\} \times L_a$
	Deg.

(To be continued.)

ELECTRICAL RESONANCE AS RELATED TO THE TRANSMISSION OF ENERGY.*

BY WM. A. ANTHONY.

Much interest is being taken at the present time in the subject of electrical resonance; and the possibility of taking advantage of this condition in the use of electrical apparatus, especially in the transmission of energy, has been discussed, and some of the conditions necessary to its successful employment have been pointed out. The conditions of electrical resonance itself have been investigated analytically, and many interesting results have been derived by various writers; and Dr. Pupin, in a lecture before the American Institute of Electrical Engineers in May, 1893, gave a most clear and beautiful popular exposition of the subject. In this lecture Dr. Pupin made most excellent use of mechanical analogies, and demonstrated his deductions by a series of very successful experiments. In this discussion Dr. Pupin confined himself to the conditions necessary to establish resonance and the effects produced when the circuits were properly tuned. He did not attempt to discuss the question of taking advantage of resonance in the electrical transmission of energy.

In a series of articles by Mr. F. W. Dunbar now (May, 1894) appearing in the *Electrical World* it is shown by mathematical analysis, that when a circuit is tuned to unison with a source of alternating E.M.F. a greater current may be transmitted to a distant point by a given E.M.F. than when the circuit is not so tuned. Although Mr. Dunbar states that his results indicate that copper may be saved in lines used for the transmission of energy, by tuning them in unison with the source, he does not point out how the condition of resonance upon the line is to be utilised for the transmission of energy, or what will be the effect upon the line were the conditions of resonance obtained.

For what follows, I propose to consider the subject entirely in the light of mechanical analogues, with which every student of physics is familiar, and shall try to point out by reference to familiar experiments with vibrating bodies just what we may expect when we attempt not only to maintain by resonance a given current upon a

* From the *Electrical Engineer* (New York).

Digitized by Google

circuit, but also what conditions must be fulfilled, and what results will follow when we attempt to transmit energy to a distant point.

I ought, perhaps, to apologise for treating the subject in the extremely elementary way I have adopted, but the principles of the transmission of vibrating motion, and the various phenomena connected with it, the formation of stationary waves, the relation of a periodic force to the motion produced by it, are so outside our ordinary experience and involve such entirely new sets of idea and new trains of thought, that I believe many readers will be glad to start at the foundation principles. I have, therefore, at the risk of appearing diffuse, detailed at some length the elementary phenomena connected with the foundation of stationary waves.

In Mr. Dunbar's articles he frequently compares a non-resonant circuit to a light, slack string, in which the wave impulses rapidly die away, and, as he says, "are absorbed by the string and their energy dissipated in the form of heat." This does not seem to me a fair comparison. A slack string does not absorb any considerable amount of energy, nothing like what is absorbed by the same string tuned to unison with the exciting source, because it is impossible to impart to it so great an amount of motion. The familiar experiments of Melde, in which the laws of vibration of strings are illustrated by the use of tuning-forks as the vibrating source of energy, will illustrate this point. So long as the string is out of unison with the fork, either from being too slack or too tense, the vibrations of the fork die away very slowly, but as the tension of the string, or its length, is varied to bring it into unison with the fork, the string will, when the unison point is reached, suddenly assume a vibration of wide amplitude, and the fork will be very quickly brought to rest. So long as the string is out of unison its motion is small and

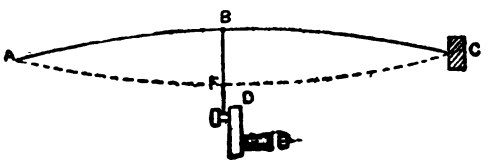

FIG. 1.

it absorbs very little energy. When in unison its motion is large, it quickly consumes the energy stored in the fork and brings it to rest. The energy of the fork is not transmitted: it is simply absorbed and dissipated in consequence of the great velocity at the antinodes of the string due to the wide amplitude. Dr. König, the well-known investigator and manufacturer of acoustic apparatus, once told me that someone had discovered and complained to him that the resonant boxes on which his tuning forks were mounted were not in exact unison with the forks. "But," said Dr. König, "if I made them in exact unison, the air would rapidly absorb the vibration, the fork would be quickly brought to rest, and then they would complain that my forks were not well going."

So in a non resonant electric circuit fed from an alternating source, a given current may be maintained by a given E.M.F. Tune that circuit to unison with the source without changing its resistance, a sudden increase of current will occur, accompanied by an increased absorption of energy, not because energy is transmitted, but because it is absorbed and dissipated by the circuit.

Let us now consider the case of the transmission of energy for some useful purpose. A vibrating string might be used to transmit energy by connecting it at an antinode to some device by which motion could be imparted to a machine. In Fig. 1, let A B C be a string attached to a fixed support at C, and at A connected to some source of energy capable of maintaining a constant vibration in the string. Let the point B be connected to a crank, D, in such a way that the vibration of the string causes the shaft, E, to revolve. It is supposed that the vibration is maintained by properly timed impulses at A, where the motion is very small compared to the double amplitude, B F, at the antinode. It is plain that the mass of the string must be such that its inertia is sufficient to more than supply the force required to revolve the shaft, E. That mass must be assumed, therefore, not only with reference to tuning the string to unison with the source of energy at A, but with reference to the work to be done. It is plain, also, since energy is force multiplied by the space through which it acts, that whatever force is exerted by the string over the space, B F, to revolve the crank, a force greater in proportion as the movement is smaller must be applied to the string at A to maintain the motion.

Again, suppose the string to be divided by a node in the middle, as in Fig. 2. The energy imparted to the revolving shaft from the point B must now be transmitted from A through the node, N. But since N is a place of comparatively small motion, the force exerted there must be proportionally large. The connection to the crank might be made from the node, N, and the power transmitted by means of the large force and small motion that occur there.

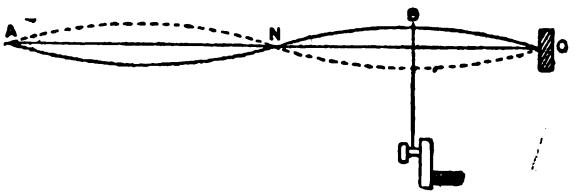

FIG. 2.

Consider now the apparatus represented in Fig. 3. Let the cylinders and connecting tubes be filled with an elastic fluid. Suppose the piston in G to have a reciprocating motion. It will alternately compress and rarefy the fluid at C D F E, and the piston, M, will be subjected to varying pressures tending to move it in synchronism with G. The apparatus is a transmission system in which G is the generator and M the motor, and C D F E the conducting circuit. If we assume the fluid to be perfectly elastic, and that no loss occurs from the compression and rarefaction, and the only loss in transmission is that due to friction in the connecting pipes.

Now we can assume for this apparatus such a fluid of such a mass and elasticity that for a certain period of vibration of the piston, G, the fluid in the pipes, C D and E F, would tend to vibrate in the same period like the air in an organ pipe, with a node in the middle, as shown by the dotted lines at A and B. In order that energy may be transmitted under such conditions, it is necessary that the fluid should have such a mass that it may in virtue of its inertia absorb the energy of the generator and then deliver it to the motor. It is no longer merely a medium for the transmission of pressure, but a medium for the absorption

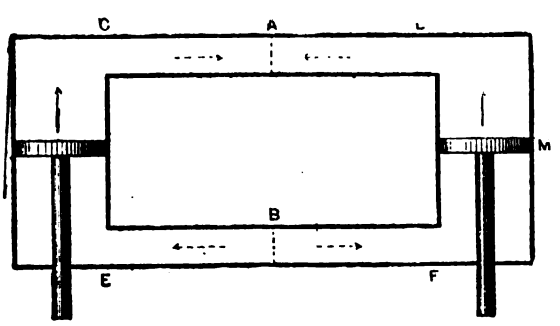

FIG. 3.

and redelivery of energy. As in an organ pipe, the nodes A B are places of comparatively little motion, the fluid on opposite sides of A and B moving in opposite directions, as shown by the arrows. Only at the ends of the pipes near the cylinder is the motion as great as in the non-resonant pipe throughout its whole length. The loss from friction in the resonant pipe is, therefore, much less, and the system of transmission is much more efficient. But since the energy must be transmitted through A and B, there must come with the diminished motion a corresponding increase in pressure. If the motion at A is one-tenth as great as near the ends at C and D, the force or pressure exerted at A must be 10 times as great.

But now the question arises, if the pipe is strong enough

Digitized by Google

to bear the pressure to which it is subjected at A, why may it not bear that pressure throughout its length, and then why not discard the condition of resonance, use the high pressure and small motion throughout the length of the pipe, and so reduce the friction losses all along the pipe to the value they previously had at the nodes? In short, the power transmitted by a belt, a cord, a fluid is the product of two factors—force or stress, and velocity. If one is diminished the other must be increased. In transmission by means of a fluid, as in the case we have considered, friction losses may be reduced by reducing the velocity and increasing the pressure to the highest practicable limit, and the least loss from friction will occur when the highest practicable uniform pressure and the lowest velocity is used throughout the length of the pipe. For, if a variable pressure is used, its mean value will be less than (since its maximum value can only equal) the constant pressure that might be employed, and the mean velocity and frictional losses must be greater than would correspond to the constant pressure.

This will be entirely clear to those who are familiar with the mathematics and mechanics of wave motion. But to make the subject plain to those who are not familiar with the mathematics let us go back to first principles and trace out what takes place in the different parts of the circuit represented in Fig. 3.

I must assume that everyone knows that when a disturbance is produced at a given point in an elastic fluid that disturbance is propagated with a certain finite velocity which is greater, the greater the elasticity, and less, the greater the density of the fluid. If a disturbance be produced at G, Fig. 3, if, for instance, G be suddenly moved toward C, the fluid immediately in front of G is moved forward, causing a compression; by this compression the motion is communicated from particle to particle at a certain definite rate, and, in a certain time, travels round the system of pipes and returns to the starting point from the direction E. This time of travelling around this system of pipes depends only upon the nature of the fluid and not at all upon the nature of the disturbance, so long as the disturbance is not too great.

Now suppose the piston, G, to be moved back and forth through a small distance just as the piston of an engine moves in its cylinder, and suppose the complete period of its vibration be exactly the time required for a disturbance in the fluid to travel completely around the circuit. When G starts towards C a wave of compression is started in front of it, and travelling through C, A, D, reaches M just as G has completed half its period—that is, just as it reaches its farthest point toward C. G then begins to return, starting a wave of compression toward E, and these two waves of compression, the one that has just reached M on the way round toward F and the one just starting from G, travelling with equal velocities, meet at B, and since the particles of the fluid at B tend to move to the left by one impulse and to the right by the other, they do not move in either direction, but the two compressions are added, causing a double compression. In consequence of this compression the particles tend to move from B in both directions, and the effect is the same as though the two impulses which met at B continued on unchanged, the one toward G and the other toward M. Following the one toward G, it reaches G, having made the complete circuit, just as the piston completes its vibration and is on the point of returning toward C. It is aided in its return by the impulse which its previous motion started, and which has just completed the circuit of the system.

But to go back to the first movement of G; when it first started toward C, and so started a compressed wave in that direction, it left a rarefied space behind it. Into this space the particles are pushed by the elasticity of the fluid, and this disturbance in which the fluid particles are all moving toward the piston moves back through E and B, and reaches M at the same time as the other disturbance travelling through C and A. Although the disturbances or wave impulses are travelling in opposite directions, they both tend to move the particles at M in the same direction, toward F, and M, therefore, moves in that direction with a double impulse. It will be noted also that both impulses reached M just as G is on the point of returning toward E. G and M, therefore, move together, the one toward E and the other toward F.

If we continue the analysis of the motion, we shall find that G and M are always moving synchronously, and the fluid is, therefore, undergoing compression in one branch at C D, while it suffers a rarefaction in the other. It will be seen, too, that A and B are planes of no motion, but of greatest rarefaction and condensation, and, therefore, greatest variation of pressure.

It will be noted that the condition that brought about this state is, that a motion of the fluid particles started by the piston, G, is transmitted from layer to layer around the circuit, returning to G just as G is ready to impart a new impulse in the same direction. This will occur if G makes one, two, or more complete vibrations during the time required for an impulse to travel around the circuit. If G makes one vibration in this time, we have the condition shown in the figure with nodes at the middle points, A and B, of the tubes. If G made two vibrations in the same time, it would be easy to show that instead of the nodes A and B there would be four nodes, dividing the circuit into four segments.

Since at each return of the transmitted movement to G it finds G ready to give a new impulse, adding to the motion already existing, the effect of the impulses at G is cumulative, and, if there were no loss from friction or otherwise, it would require but a few small impulses at G to set up a powerful vibratory motion in the tube. Assuming that there was no friction and no energy taken from the system in any way, such a vibration once started would never cease.

It will be plain that when this vibration has become established all the particles of the fluid between G and A and between M and A move toward or from A simultaneously, and that as we recede from G or M the amplitude of the motion continually decreases until at A it is zero. Such a wave, in which all the particles between two adjacent nodes move simultaneously in the same direction, is called a stationary wave.

But while the particles at M and G move over the greatest distances, the particles adjacent to these move over so nearly the same distance that there is very little approach or recession and consequently very little change of pressure, while the contrary is the case near A and B.

Consider the particles at G and M to be moving at their greatest velocities toward C and D through their positions of equilibrium. They are gradually brought to rest at the extreme point of the vibration by the small opposing elastic force of the fluid. Their kinetic energy is absorbed by a small force acting over a comparatively large space. As we go toward A, however, the space becomes less and less, and the force, as it should do, becomes greater and greater. It may be considered that the kinetic energy of the particles at M is transferred from particle to particle back through D and A toward G. At the same time the kinetic energy at G is transmitted through C and A toward M. On the supposition that no energy is lost to the system, an equal amount of energy is transferred through A in each direction, and the particles at A remain at rest.

Now suppose the particles or piston at M be called upon to do outside work. On the same supposition as before, that M is moving toward D, since part of its energy is consumed by the outside work only a part is transferred through A to G, hence G receives less energy from M than would have been received if M had not done any outside work.

There is then a lack of energy to maintain the vibration at G, and unless energy is supplied, the whole system will soon be brought to rest. Let energy be supplied to G. It must come from a periodic force tending to maintain the vibration. Such a force acting upon G through its amplitude imparts energy to the fluid which is transferred through A and B to M to make up for that taken away from M. But now since more energy is transmitted in one direction than the other through A and B, the particles there can no longer remain entirely at rest. The amount of motion at A and B will depend upon the relation that the excess of energy transferred in one direction over the other bears

Digitized by Google

to the whole energy transferred, and in order that the nodal character of A and B may be maintained, it is important that this excess of energy should be small compared to the whole.

This leads to a most important consideration, that if the resonant character of the system is to be maintained the energy taken from M must be only a fraction of that stored in the vibrating system. It should be noted, further, that when energy is taken from M, and consequently motion takes place at A and B, the motions of G and M, although always isochronous, are no longer synchronous, and the departure from synchronism is greater as the amount of energy used is greater.

Bearing in mind the relative motions of the various particles of the vibrating fluid, it will now be clearly seen that the energy required to make up for that lost to the system, which is applied in the form of a force acting through the comparatively large space represented by the amplitude of vibration at G, as it is transferred toward A and B to particles whose range of motion is less and less, must appear as a greater and greater force acting through a smaller and smaller space.

Considering now that when vibration takes place without loss to the system the nodes A and B are places of great elastic stress, while at G and M there is almost no stress whatever, and that when force is applied at G to make up for the loss in the system, that force is magnified at A and B and appears there as an added elastic stress, it becomes evident that under such a system of transfer of energy the pressure at the nodal points must be many times greater than elsewhere in the system.

We may now apply these considerations to an electric circuit. Difference of potential or electric stress corresponds to pressure or elastic stress in fluids. Electric flow corresponds to fluid flow. Electric current corresponds to velocity. Self-induction is a sort of electric inertia corresponding to mass inertia. Elasticity in a fluid corresponds to the rate of change of electric stress with charge. That is, the elasticity of a fluid is the ratio of any small change of pressure to the corresponding change of volume. So we might call electric elasticity the ratio of any small change of electric pressure to the corresponding change of charge. Obviously the change of pressure (electric) due to the unit change of charge will be inversely proportional to the capacity of a body.

It is obvious that an electric impulse or displacement will travel on a conductor with a perfectly definite velocity depending upon the electric inertia or self-induction which tends to hold back or retard the motion, and the electric elasticity which tends to hasten it. Such a propagation results in a stationary wave if impulses are properly timed, precisely as in a vibrating string or organ pipe, or in the fluid circuit represented in Fig. 3. Such a stationary wave must have its nodes where there is no current, just as the string or organ pipe has nodes where there is no motion. That such nodes exist in a resonant electric circuit is demonstrated by the fact that less energy is lost on a resonant circuit than on a continuous-current circuit carrying the same current as exists at the terminals of the resonant circuit. For, since the energy lost in the resistance of the circuit is C^2R, the loss can only be diminished by diminishing C, and if $C^2 R$ is less on the resonant circuit than on the continuous-current circuit, it is plain that the mean C^2 must be less, and hence that C along the line of the resonant circuit is less than at the terminals. In fact, if we assume a simple harmonic wave and nodal points of absolutely no current, the current strengths along the circuits will be represented by a sine curve, and the mean C^2 is in that case just half the maximum C^2. Hence, just half the energy is saved, or we can waste the same amount of energy and save 50 per cent. of the copper in the line.

Such a mode of absolutely no current cannot, however, exist if any energy is lost to the system either as waste, dissipated from conductors, or as useful energy taken from translating devices. In this case, just as in the vibrating string or fluid circuit, more energy is transferred through the node in one direction than in the other, and this cannot be without some current. It is plain, therefore, that in any practical system of transmission not quite half the copper can be saved by tuning it to resonance.

But let us consider the other conditions that must exist on a resonant circuit.

Just as we have already found for mechanical resonance, so in electrical resonance, the inertia must be large in comparison to the energy to be taken from the system. In other words, in order that resonance may be maintained, the self-induction of the circuit must be such that energy may be stored in it, in amount several times what it is proposed to take away. This requires a relatively large electrical elasticity, which may be obtained by making the capacity small.

As in the resonant fluid the nodes of no motion are the places of greatest pressure, so in the electric circuit the nodes of no current are places of greatest electric stress. In other words, the antinodes of the curve of stress correspond to the nodes of current, and *vice versâ*.

It will be remembered that the condition of resonance in the fluid system of Fig. 3 was that any given movement started by the piston, G, must, after travelling completely round the circuit, return to G to find the piston moving in the same direction—that is, the impulse given by the piston must always coincide in direction with the motion the fluid already has from previous impulses. So with the electric circuit, and for the same reason, the condition of resonance is that the impulses given by the generator to compensate for the energy taken from the system must always coincide in direction with the current already established; or, in other words, the phase of the impressed E.M.F. must coincide with that of the current. But just as the pressure exerted by the piston, G, is multiplied as it passes through the nodes A and B, so the electric pressure of the generator must be multiplied as it passes through the points of minimum current. These points are, therefore, for two reasons, points of many times greater electric stress than exists at the terminals of the line, and the question at once arises, as in the case of the fluid transmission, if the insulation of the line will bear this great electric stress, why not so design the system that this stress, with its accompanying small current, shall exist throughout the line.

All this might have been said in a very few words. Everyone familiar with the characteristics of harmonic vibration and wave propagation knows that the force is a maximum when the velocity is a minimum, and the velocity a maximum when force is a minimum; and that for all stationary waves, the two curves representing respectively force and velocity at different points, the ordinates of one are always a maximum where those of the other are a minimum.

An electric circuit tuned to resonance with the generator, affords an example of a stationary wave where the maximum current is at the generator and motor and the minimum current at the nodes on the line. This gives a minimum of energy consumed in the transmission. But the E.M.F. curve has its nodes at the generator and motor, and its antinodes correspond to the nodes of the current curve on the line. Therefore, whatever the electric pressure at the generator and motor, they must be small compared to the pressure on the line at the current nodes.

While, therefore, a line tuned to resonance with the source may transmit energy with less $C^2 R$ loss, we must, to secure that result, give to it a self-induction capable of storing several times the energy it is proposed to transmit, and subject it to electric stresses several times what would be required with the same current to develop the power consumed.

Electric Transmission at Buccari.—The authorities of the little town of Buccari, near Fiume, which has only 3,000 inhabitants, but which is coming into notice as a health resort and bathing-place, have made use of water power for providing for the public and private electric lighting of the town. The installation has been carried out by the International Electricity Company, of Vienna. A Ganz turbine is employed, and in addition there is kept as a reserve a 20-h.p. steam-engine. A 6,500-watt continuous-current dynamo supplies current at a pressure of 100 volts. There are 50 incandescent lamps in the streets, and about 120 in private houses.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

A NICE PROBLEM.

It is not possible for us just now to discuss the history of Woodhouse and Rawson United, Limited, but there are questions of a general character which, without trespassing upon the jurisdiction of the Court, may perhaps be discussed. When does a debt become a debt has created a diversity of opinion in respect to a correct answer, or, rather, when does a profit upon a commercial transaction become a profit? From the accountant's point of view there ought to be no difficulty in determining the time, but in this, as in every other case, the exception may prove the rule. It seems to us that if Messrs. A., B., and Co. on the last day of their financial year—nay, if you like, during the last hour of that day, or the last minute of that day, sell a dynamo to Messrs. C., D., and Co., the profit or loss accruing from that transaction belongs to the financial year in which the transaction is concluded. The dynamo no longer belongs to Messrs. A., B., and Co.: it cannot be valued as stock, but must appear, if the transaction is *bonâ fide*, as a good book debt. Thus, as a good book debt it goes to swell the assets of the firm, and assists in making the total assets. So far, we imagine, all are agreed, but the agreement is not so general when something less tangible is bought and sold. But should this be so? Let Messrs. A., B., and Co. sell a mine for money and shares at a similar period of their financial year. Ought they to ignore the transaction in the balance-sheet, or to take the sale price as a good asset—a good book debt? Undoubtedly the safest way would be to treat the matter in a suspense account, but is there any legal or moral necessity for doing this when the transaction is *bonâ fide*? Yes, say a large number of people—apparently the larger number—for paper shares should never be treated exactly in the same way as cash, or commercial bills, or debts for goods supplied; there is never any absolute certainty as to the value of shares till they are quoted in the market. These opinions are not unimportant, because in many cases business men are almost compelled to take shares or debentures or some such security for a debt for which they cannot obtain cash. Again, the safest plan is to put the amount to a suspense account; but is this always possible? The business man may be convinced that the face value of the security is its real value; and in an estimation of his affairs is he to ignore that which to him is as safe as the Bank of England? To electric light engineers the question is of great importance. Many good enterprises now in thorough working order could not have been started unless part payment had been made in shares, and if the recipients of these shares had to treat them as bad debts, or as something not forming an asset, their affairs would not be too promising. During the past ten or fifteen years enormous numbers of shares have thus been paid over and have been accepted as assets. In many instances, too, these shares have realised their face value, but, of course, in many others they have never realised a cent. The nice problem for the moment is how and when and at what price such shares should

Digitized by Google

appear in the books of the firm or company. We incline to the opinion, that in the case of a sale when the sale is completed—that is, upon the day when the books record the transaction. If, for a central station cash and shares are to be taken, the profit or loss upon the transaction cannot be taken on the day when the agreement for the station is signed and sealed. In the ordinary course of book-keeping for balance-sheet purposes, the amount expended at the close of the financial year would be estimated, and if the necessities of the case demanded a proportional profit on that expenditure might be assumed to have been earned; but further than this no one ought to go. The difference between this total and the amount received on account would, of course, figure in the books as a good debt. There are many funny little business transactions of this kind that would form good subjects for discussion by the Electrical Section of the London Chamber of Commerce, but that body is not altogether immaculate in eagerness to touch outside business, or preferably we may call them detail business questions.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

OIL FUEL AT HULL.

SIR,—Kindly allow me to correct an error in your issue for July 6, with reference to my report to the Electric Lighting Committee on "oil fuel." In the fourth sentence it is stated that "Messrs. Laycock found that at 1*s.* 4*d. per gallon* oil fuel was equal to coal at 12s. per ton." This is an obvious error for 1½*d. per gallon*, as in the following sentence the words *not exceeding* 1*d. per gallon* are correctly reported.—Yours, etc., ALFRED H. GIBBINGS.

Hull, July 6, 1894.

[The paragraph referred to was given on pages 26 and 27 of our last issue.—ED. *E. E.*]

GAS v. STEAM FOR CENTRAL STATIONS.

SIR,—I have read your opportune and interesting article on "Gas *v.* Steam for Central Stations," which appeared in your impression of July 6, 1894. The tabulated data of comparison contains many serious discrepancies, and of such an obvious character as to absolutely destroy their value for reference purposes.

For instance, in comparing the cost of the preliminary installation of 160 h.p., the six-ton overhead traveller is stated to cost £200 in the steam installation, and £300 for the gas installation. In the complete installation of 1,400 h.p. the cost of gas-engines and dynamos is given as equal to £12,820, whereas the Willans engines and dynamos for the same power is given as equal to £10,825. I think any unprejudiced engineer who understands these matters knows this to be a misleading and unfair statement.

In the working expenses (preliminary installation), the coal for the gas plant is stated to be 24s. per ton, whereas the steam coal is fixed at 6s. per ton. Surely there is not such a discrepancy between the cost of anthracite and steam coal as is here indicated, not to say we have heard of a gas producer using coke. In the complete installation working expenses account the water for the steam-driven plant is stated to be 4,000,000 gallons, at 7d. per gallon, costing £117, whilst the 500,000 gallons of water used for the gas-driven plant are stated to cost £150.

There are other equally misleading figures which if corrected would prove that the gas plant, both in first cost and in working cost, would be very considerably the more economical of the two plants.

If the gentleman who has drawn up the tabulated data is interested in the subject, and is anxious to find out the real advantages of gas plants over steam, I shall be glad if he will call upon me, when I shall be pleased to show him an electrical installation being erected to be driven by a gas-engine, and gas plant to burn slack coal.—Yours, etc.,

G. THRELFALL, Chief Engineer,
The Motor Gas Plant Syndicate.

London, E.C., July 12, 1894.

REVIEWS.

Electricity One Hundred Years Ago and To-Day. With copious Notes and Extracts. By EDWIN J. HOUSTON, Ph.D. (Princeton). New York: The W. J. Johnston Company, Limited, 253, Broadway.

The author of this work, in tracing the history of electrical science from practically its birth to the present time, has, as much as possible, consulted original sources, and he was fortunate in having at his disposal the library of the Franklin Institute, which contains one of the most complete collections of scientific publications of the last century. As a result of his researches, several revisions as to the date of the discovery of some important principles in electrical science are claimed to be necessary. The compass of the book does not permit of any other than a general treatment of the subject, but at the same time numerous references are given in footnotes, which would better have been embodied in the general text. One of its admirable features is the agreeable style in which the work is written, its philosophical discussion as to the cause and effect of various discoveries, and its personal references to great names in electrical science.

THE NEW TELEGRAPH CABLE IN THE ST. GOTHARD TUNNEL.

A recent issue of a French contemporary contains an article dealing with this new cable. It appears that the first telegraph cable for the St. Gothard tunnel was made by Messrs. Felten and Guilleaume, of Mulheim-on-the-Rhine, and was laid in 1882. In the year 1890 the St. Gothard Railway Company put down for their own service a telegraph cable with three conductors, and also a concentric telephone cable. Although the older cable was thus relieved, the Swiss telegraphic authorities found it necessary to lay another cable during September and October, 1893. The conditions present inside the tunnel render great care necessary. The water trickling down the walls contains sulphuretted hydrogen, sulphur dioxide, ammonia, and carbon dioxide, besides other products from the smoke of the locomotives. The conditions are so bad that even the rails and sleepers themselves have been affected. The temperature of the tunnel reaches 73·5deg. F. at the middle. It was essential to have a strong protective covering, as workmen are continually employed inside the tunnel, where labour is very difficult. The Swiss Telegraph Department has spared no expense in obtaining a satisfactory cable for the international telegraphic communication. Messrs. Felten and Guilleaume were chosen as contractors, and the cable was formed of six conductors grouped around a central conductor. Each of these consisted of seven copper wires of 0·097in. diameter properly stranded together. Each conductor was insulated with alternate layers of Chatterton compound and guttapercha to a diameter of 0·235in. The whole seven conductors formed a cable, which was covered with bitumenised ribbon, and over this was placed a double lead covering to keep out water. Other layers of insulation were placed over the lead pipes, and the whole was protected against injury by a layer of 25 iron wires of Z section wrapped over one another. The layer was protected externally by a spun covering impregnated with a preservative compound. The cable has an external diameter of 2·05in., and a total length of 9·8 miles, divided into portions about 815 yards long, and each weighing 15·14 tons. Besides the main cable, some short lengths having four or five conductors were also required. The

Digitized by Google

cable was laid under the superintendence of Dr. V. Wietlisbach, of Berne, and it was decided to place the new cable in the same trench along with the old ones. The latter were therefore covered with sand, and the whole finally filled up with sand and covered with flagstones. Owing to the large amount of traffic upon the line, the work of laying the new cable could only be proceeded with between 7 p.m. and 9 p.m., and the joints had to be made during the night. The extremities of the cable are situated at Göschenen and Airolo, and are fitted with lightning protectors.

The prescribed conditions are given in column 1, and those found by actual experiment in column 2:

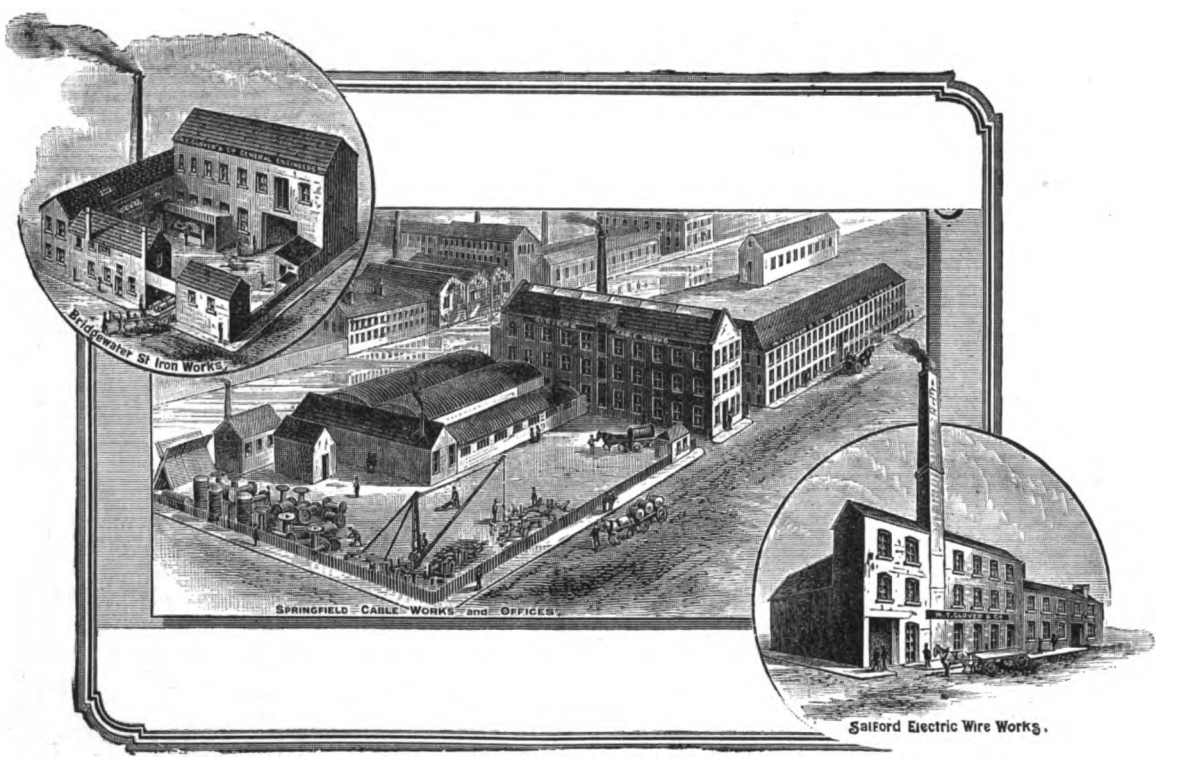
—	Column 1. Per kilometre.	Column 2. Per kilometre.
Lineal resistance of the copper not to exceed	7 ohms	6·55 ohms
Insulation resistance not to be below.....	1,000 megohms	7,500 megohms
Lineal capacity not to exceed.....	0·25 microfarad	0·193 microfarad

MESSRS. W. T. GLOVER AND CO.'S EXTENSION OF WORKS.

The increasing business of Messrs. Walter T. Glover and Co., of Salford and London, the well-known electric wire and cable makers, has necessitated the provision of new offices and storerooms, which have been erected contiguous to the company's Springfield Cable Works in Salford. The opening of the new buildings was recently celebrated by Mr. Henry H. Edmunds, the principal, who gave a supper and entertainment to his staff and employés.

A reference to the company's price-list of electric light wires and cables shows the large variety of manufactures turned out at the Salford works, an illustration of which is annexed. The vulcanised wires and cables, immediately after vulcanising, are immersed in water, and after a period of 24 hours they are tested at a temperature of 60deg. F.; until they have passed satisfactorily through this test they are not subjected to any further process of manufacture. When coils are issued from the works, they are accompanied by a certificate from the electrical department. The company also make lead-covered cables and concentric cables, in addition to a large assortment of telephone, telegraph, and multiple cables, which are detailed in a separate list, and cotton and silk lapped high-conductivity copper and German-silver wire for dynamos, transformers, resistance coils, bells, etc. Among other manufactures may be mentioned the company's patent armature bars having solid ends. This method is a great improvement on either brazing or soldering. The bars and solid ends can be made to any required shape, and the solid ends may be of the same shape as the bar itself, or they may differ from it to suit any special connections.

On the occasion of the above-mentioned ceremony nearly 400 people sat down in one of the sheds to an excellent repast, the room being decorated, and on a platform at one end arrangements were made for a musical and conjuring entertainment. During the course of the evening Mr. Edmunds took the opportunity of welcoming all present, and reminded them of the growth of the business, and of the necessity of individual care on the part of all present in connection with every detail of their large but important manufacture in connection with electrical cables. He expressed the hope that a meeting of this kind would be productive of a good understanding between master and man, which, judging from the hearty response on the part of all present, would augur well for the future relations of the business. An excellent conjuring entertainment was given, and a Bradford young man surprised those present by his clever execution on the violin. During an interval the employés inspected the new dining-rooms and lavatories, and also the new offices which have been constructed in the buildings adjoining Glover's old cable works, and have a frontage extending some 190ft. In addition to the offices and warehouse, stores are provided for raw materials, such as cotton and copper, and for the finished manufactures, such as electric light cables, wires, telephone and telegraphic materials, etc.



Messrs. Glover and Co.'s Works.

THE TRAMWAYS INSTITUTE.

A general meeting of this institute was held on Thursday of last week at the Holborn Restaurant, there being an attendance of 50 or 60 members and visitors, under the presidency of Mr. W. J. Carruthers Wain. The first part of the proceedings was largely of a formal business nature, and included the adoption of the report and balance-sheet for the past year, the election of certain officers (amongst whom should be named Mr. Wain, re-elected president of the institute), and other items of a similar kind. There next followed the reading and discussion of several papers concerning tramway topics. One of these was by Mr. F.

Purdon, C.E., upon the important, yet sometimes overlooked, matter of car bearings. This contribution we abstract as follows.

Roller Bearings for Tramcars.

BY F. PURDON.

The advantage of having good tramcar bearings is obvious, and a great many efforts have been made to improve them, either by alteration of the form and materials of the bearings, or the method of lubrication. These efforts have met with more or less success, but even when the best of them are employed, the tractional force necessary to start a car and maintain its speed is very high; probably only the horse knows how high. I have endeavoured to get some reliable estimate of what this tractional force is, but have found authorities differ widely owing mainly to the varying conditions under which the experiments have been made. Mr. D. K. Clark, in his valuable work on tramways, gives as an average 25lb. as the tractional force required to keep one ton moving continuously, and the starting effort as 50lb. per ton, or double. For the present I think it will be admitted that the work the tramcar horse is asked to perform is very severe, and although his daily mileage (about 12 miles) is not high, his life is short, which fact is no doubt due to excessive strain upon his muscles.

The cyclist, who has been put much in the same position as a horse, but who has the advantage of being able to speak and demand alleviation, very early discovered the advantages to be derived from roller bearings, and the universal adoption of the ball bearing for cycles is the result. The ball bearing, however, admirable as it is for the light weights carried on the cycle, has never succeeded under heavy loads, owing mainly to the fact that all the weight is carried by only one or two balls at any moment of time, and the balls only touch the races, or ball paths, on a point, the result being that either the balls crush or the races are indented. The ball bearing, from its design, requires lubricant, which is in itself a collector of dirt, and in large vehicles is also an item of considerable expense. In a true rolling bearing—that is, one in which there is no scrubbing of parts—no lubrication is necessary, and the fact of lubrication being wanted or not becomes a test as to whether a bearing is a true rolling bearing or not. That lubrication is not required for rolling motion is shown by the fact that we do not put oil or grease on the rail, and yet the periphery of the wheel, where it is in contact with the rail, has a much greater speed than has its boss where it touches the journal, but this latter requires much lubrication. The explanation is that in the first case there is rolling motion, and in the second sliding or scrubbing motion.

In connection with my partner Mr. Walters and Mr. Woodcock, the bearing now to be described has been devised, for which it is contended that it is fully capable of bearing the weight of a tramcar, that it requires no lubrication, that it has no sliding or scrubbing parts, that it shows great endurance, and gives remarkable ease of traction. Great reduction of working expenses must result from its application to tramways, and it therefore in my opinion needs no apology for presenting itself before this institute. The conditions of a good roller bearing are severe.

(1) Sufficient bearing in lineal inches must be provided to bear the weight, which in the case of a tramcar may be taken as 1¼ tons per bearing. It is this condition which prevents the use of balls, and compels the adoption of rollers, which can be made the whole length of the journal.

(2) The rollers must not move laterally, and must remain exactly parallel with the journal, from which position the least deviation reduces contact to a point and sets up a spiral movement of the whole series of rollers upon the journal.

(3) The rollers must not touch one another, as if they do (like balls in a ball bearing) the surfaces in contact revolve in opposite directions, and scrubbing must take place and lubrication be required.

(4) No dust must be allowed to get in, though dirt or dust is not so injurious a factor in roller bearings as it is in oil-boxes.

(5) No sliding or scrubbing must take place between the parts of any device for the separating of the rollers, otherwise the evil is only removed from one place to another,

(6) The journal must not move laterally under the load, as this would set up the spiral movement referred to above.

The above conditions, it is claimed, are all met by the bearing now to be described.

Rollers are provided to carry the weight. They are driven by the axle, and are the full length of the journal. Knobs on subsidiary rollers act as spacers to keep the main rollers from touching each other. These subsidiary rollers are driven by the main rollers, and effect a similar condition as would occur if teeth were provided in the axle, rollers, ring, and path. The speed at which the "knobs" are driven is regulated by the diameter of the main rollers at the points of contact, and this is so proportioned that the subsidiary rollers perform one revolution round their orbit (which is the path contrived in the end covers) in the same time as the main rollers perform one revolution round their orbit, which is the casing of the bearing. The subsidiary rollers do not touch the casing, and they are prevented from moving inwards by the "path," and outwards by a "live ring," which embraces them, and which they drive at their own speed. Lateral motion is prevented by the "knobs" on the subsidiary rollers, which are so constructed that they engage the rollers and the "path" at their normal diameters, so that there is nothing in the nature of a flange which involves scrubbing. End movement of the axle in the box is prevented by single balls at each axle end, which roll truly, and have an adjustment by which the rollers and the journal are always kept in the same relation to each other. In order to allow of some end play, which in the ordinary box is managed by collars on the brass and journal, the box is carried on a trunnion, and as the centre line of the box is not exactly coincident with the centre line of the spring, some play is given in the guides, but without allowing the axle to slide under the rollers. This arrangement works admirably in practice, and its effect is very noticeable to anyone riding in the car, as instead of the jolt which we are familiar with at points, or other irregularities in the road, a gentle swing of the car is all that is felt. This arrangement is mainly due to Mr. Greg, the superintendent of machinery at the Lancaster Carriage and Wagon Company's Works; and it did much to overcome a difficulty that occurred in the early experimental bearings in connection with end play.

Passing now to practical experiments, Mr. W. Shackleford, the general manager of the Lancaster Company, who has taken a warm interest in the bearing, has made a large number of practical experiments. He has made and run a railway wagon with results as reported in the *Engineer*, April 14, 1893; also bearings for line shafting, dynamo shafts, and others (with which I do not intend to trouble you to-day), before taking the tramcar in hand, and after a good deal of experience had been gained and many difficulties surmounted, a set of tram boxes was made, which have worked admirably. These were fitted to a truck, and the following tests were made for starting effort, compared with a similar truck having ordinary oil-boxes. The trucks were loaded up to 4 tons 15cwt., and a piece of line was selected on a gradient of 1 in 44, with a long straight and level piece at the bottom. The trucks were let go from the same height up the gradient, and the distances they travelled were measured. The next test for starting effort was by standing the truck on the level, with a cord attached, passing over fixed pulleys, and measuring the starting effort by placing weights in a basket at the end of the cord. The following table will show the results of these tests.

1. GRAVITY TEST.—Cars let loose from a point 44ft. up an incline of 12⅜in. rise:
   Ordinary box ..... 33ft., average of three runs.
   Roller-box ..... 211ft., " "
   Result ..... 6·39 to 1.

2. GRAVITY TEST (*continued*).—Cars let loose from a point 56ft. up an incline with 1ft. 6½in. rise:
   Ordinary box ..... 57ft., average of three runs.
   Roller-box ..... Ran into stops at about 320ft.

3. STARTING TEST.—Amount required to start by falling weight:
   1. Ordinary box ..... 81lb. Roller-box ..... 18½lb.
   2. " " ..... 75lb. " " ..... 24lb.

4. STARTING TEST.—As above, but with a weight of 4 tons 15cwt. on truck:
   Ordinary (by former trial) ..... 198lb.
   Roller ..... 31lb.
   Result ..... 6·39 to 1 (as before).

Digitized by Google

A saving will also be effected on gradients both in starting and running, but the proportion of saving will, of course, decrease as the incline increases. The following table shows the estimated saving in percentages of tractive force for gradients from 1 in 20 to 1 in 140:

COMPARATIVE TRACTIVE FORCE required to start a tramcar of five tons total weight, fitted with ordinary oil bearings and with roller-boxes, on various gradients.

Gradient.	Tractive force. Oil bearings in pounds.		Tractive force. Roller bearings in pounds.		Saving per cent. by use of roller bearings.
1 in 20 ...	Gravity	560	Gravity	560	
	Friction	125	Friction	21	
		685		581	15·2
1 in 50 ...	Gravity	224	Gravity	224	
	Friction	125	Friction	21	
		349		245	29·8
1 in 80 ...	Gravity	140	Gravity	140	
	Friction	125	Friction	21	
		265		161	39·25
1 in 110 ...	Gravity	102	Gravity	102	
	Friction	125	Friction	21	
		227		123	45·8
1 in 140 ...	Gravity	80	Gravity	80	
	Friction	125	Friction	21	
		205		101	50·7

The above table is founded on the supposition that the frictional resistance to traction in cars fitted with ordinary oil-boxes is 25lb. per ton, and in cars fitted with roller bearings only 4⅕lb. per ton, which figures are in accordance with the results of the experiments made at Lancaster. Frictional resistance will therefore be 125lb. for a car of five tons gross weight in the former case, and 21lb. in the latter.

The next thing was to get the bearings attached to a car in actual work, and to see how it behaved on the curves and under the stresses to which such cars are subjected. This was done by permission of the Morecambe Company, where the car was put to work in February, 1894, and ran for about two months, or, say, 3,000 miles, giving great satisfaction. The ease to the horses was quite unmistakeable, and the trunnion arrangement worked admirably. At the end of this time the boxes were taken off and examined and were found quite unworn. While running at Morecambe they were inspected by Mr. Holroyd Smith, the engineer to the Blackpool Corporation electric tramways, who was struck by their ease of running; and he made the following suggestion—viz., that as no precise result, showing the relative advantage of roller bearings as against ordinary boxes, could be obtained under the condition of horse traction, the roller-boxes should be placed under one of his cars on the Blackpool electric tramways, where the amount of current required to drive the car fitted with the roller-boxes could be measured as against a car fitted with ordinary boxes. Mr. Smith has since reported as follows: "I find that the power required to drive car No. 6 with the roller bearings is fully 30 per cent. less than the power required for car No. 5 with ordinary bearings. I have reported above to the Tramway Committee, who consider it so satis factory that they have instructed me to order roller bearings for the two bogie cars now being built."

The first cost of these bearings is undoubtedly high, but when made in quantities they can be supplied at a reasonable cost. Moreover, there are many ways of realising undoubted advantages in traction, so as to pay for the greater first cost of the roller-boxes, and also to improve the dividend-paying power of companies when these boxes are used. Taking a hypothetical case of a tramway six miles long, with a 10-minute service all day, and assuming that it takes a car 2 hours and 20 minutes to make the round journey, there will then be 14 cars on the road when in full work, and supposing that the first car leaves the depôt at 8 a.m., and the last at 9.50 p.m., then there will be 84 car journeys per diem, and the total car mileage will be 1,008. If each pair of horses is worked 12 miles per day with one day off in seven, then the total number of horses required to work the foregoing traffic will be 196. If by the introduction of roller-boxes the traction is so much reduced that each pair of horses is able to travel 16 miles per diem with six days off in 28, then the total number of horses required to work the traffic will be 160, showing a saving of 36 horses, or 18·4 per cent., which at the rate of £55 per horse per annum for keep and renewals, would show a total saving of £1,980 per annum, or 1·28d., say, 1¼d. per car mile, without considering the saving in the cost of lubricant.

Tramway working expenses absorb so large a proportion of gross receipts that any saving in the latter soon becomes appreciable in the dividend payable; 55 per cent. of the average 80 per cent. representing total expenses is due to horses, showing that that is the item where saving will be the soonest appreciable in dividend. Assuming a tramway paying 5 per cent. dividend, with 80 per cent. working expenses, then 20 per cent. gross receipts equal 5 per cent. dividend, and a reduction of 4 per cent. working expenses will equal 1 per cent. dividend. Now, taking 55 per cent. of the working expenses as due to horses, and reducing the number of horses by 18 per cent. as above, there should be a saving of 18 per cent. of 55 per cent., or about 8 per cent., reducing working expenses to 72 per cent., and increasing dividend to 7 per cent. instead of 5. These figures are hypothetical, but they cannot be gainsaid on broad lines, and they show clearly that there is a great advantage to be derived from reducing the work and consequent number of horses. Similar conditions, of course, apply in the case of lines worked by mechanical powers.

In asking the members to give their opinions upon this communication, the PRESIDENT said that for his part he would undertake to afford Mr. Purdon any opportunity he might desire to try the device on the lines with which he (the president) was connected.

Mr. WHYTEHEAD (North Staffs.) said that he had tried a bearing with one roller in it some two years ago, and found that it made a great difference in the starting effort required. He could not, however, detect any great saving in the coal bill, owing to the necessarily dirty roads and rails throughout his district.

Mr. PURDON stated that the extra cost of the bearing would be about £10 per axle, though this might be reduced when making quantities.

Mr. HOLT (Crossley Bros.) spoke favourably of the device from a theoretical standpoint.

The last-named gentleman was next called upon to read a short communication which he had prepared on the subject of gas motors for tramways. This dealt chiefly with the requirements and conditions of such, concluding with a few particulars of the Lührig gas motor now under trial on the Croydon tramways. The cost of fuel used in such a system was stated by Mr. Holt to be about 1½d. per car mile, and the capital expenditure, including station plant, about £600 per mile.

In a brief discussion which followed, Mr. ALFRED DICKINSON (South Staffs.) said that the cost of fuel in such a case was not any lower than when steam-engines are employed, and he gave these figures to show comparison between the various systems:

	Cost of fuel per car mile.
South Staffs., steam motors	2·34d.
Birmingham ,, ...	1·81d.
Dudley and Stourbridge ,, ...	1·94d.
Birmingham Central ,, ...	1·92d.
,, ,, electric accumulator	1·76d.
,, ,, cable	1 60d.
South Staffs., electric overhead	·48d.

Mr. Dickinson was announced on the agenda to read a paper on "Electric Traction," but owing to the details contained therein being also embodied in a prior communication (not yet published) to the Institution of Civil Engineers, he was prevented from bringing forward what would without doubt have proved a most interesting subject for debate. There was no desire evinced by the

Digitized by Google

members (at the late hour to which the proceedings had by now attained) to take up the adjourned discussion upon M. Victor Popp's paper, "Traction by Means of Compressed Air," read at the previous meeting, and it was again postponed.

SOME STORAGE BATTERY PHENOMENA*.

BY W. W. GRISCOM.

(Continued from page 17.)

A curious feature in charge is the intersecting of the curves of the positive and negative plates at several different points. At the beginning of charge, the two plates are at nearly the same potential, the positive potential rises rapidly until it reaches 2·22 volts, when it begins to rise in a straight line strictly proportional to time. The negative, on the other hand, rises gradually until it reaches 2·18 volts; then it rises rapidly, intersecting the positive curve in 14½ hours and at 2·24 volts, and continuing to rise until it reaches 2·40 volts in 16¾ hours, whereafter it remains constant for the five hours which the positive requires to reach the same potential.

To trace the history of a negative during discharge, it fell in five minutes ·135 volt, in the next six hours ·035 volt, in the following hour ·250 volt, and in 15 minutes more 1·500 volts, showing less capacity than the positive plate. In half an hour after stopping discharge it recovered to 1·9 volts—jumping instantly on charge to 2·08 volts, and in 12 hours of charge arose only ·05 volt. Of course the rate will not modify the general characteristics of the curve.

Within the working limits of charge or discharge, the negative did not vary over 2 per cent. of potential difference.

The history of the positive in this curve is not so satisfactory. Falling rapidly to 2·04 in 10 minutes, it fell thereafter in a gradual curve ·115 volt during the normal time of charge, a fluctuation of about 6 per cent. Ultimately the positive shows more capacity than the negative.

The total fluctuation of the cell during the six hours after the first five minutes was 6 per cent. in discharge down to 1·9 volts. This was the fluctuation of the potential difference—that is to say, it was the fluctuation which would be noticeable to the engineer in practical service, and included all changes due to internal resistance.

The usual construction of storage batteries—all the plates of one name being permanently fastened to one heavy conductor—has heretofore interfered with the study of the individual plates of a cell. To the end, therefore, of facilitating this investigation, the author constructed some cells with independent plates, connecting all those of one name to a common mercury trough, either directly or through intermediate resistances.

The resistances were made such that one ampere would give 10 divisions on a dead-beat galvanometer, and as each division could be divided by the eye into tenths, the current passing could be read within one-hundredth of an ampere. An independent ammeter and an adjustable mercury resistance were inserted, and the total current kept constant. The cells tested in this way were of three types—the pasted cell of the Accumulator Company, the chloride cell, and the Planté cell. The object in testing a chloride cell was to ascertain whether the exceedingly good contact produced by casting the grid around the active material while the latter was hard, and allowing the molten metal to contract upon it, would operate to lessen the somewhat remarkable variations in the behaviour of all storage battery plates. But this was not the case, neither was there any marked difference in the behaviour of the Planté cell. The accompanying characteristic readings were obtained from the three types of cells at their normal discharging rates.

A. Amperes. V. Volts.

The curious phenomenon was presented of variations of current amounting to 30 per cent. in plates manufactured rigorously alike, kept in parallel and subjected to like treatment during their previous life. In cases where the discharge is pushed below 1·8 volts I have observed even more serious differences, amounting to a variation of 225 per cent., one reading being 2·8 amperes, another 6·4 amperes for perfectly good new plates carefully treated.

And perhaps a still more curious fact was the differences of E.M.F. of the plates in the same cell discharging through equal resistances and connected finally in parallel to the same circuit—the E.M.F. ranging from 1·60 volts to 1·85 volts for neighbouring plates in parallel in the same cell, at the same time. On interrupting the circuit at the end of the discharge of a cell, a considerable flow of current, as might be expected, passed from one plate into another, and it was hours before the batteries reached equilibrium after the external circuit was open.

The discharge of one positive into its neighbour was a rather unexpected result. It had been thought that if one plate had less capacity than its neighbour it would simply stop discharging at a certain point, but that its E.M.F. would always be equal to that of its neighbours, and that therefore no current would flow.

The explanation of the phenomenon appears to be that the deficient plate keeps on discharging at a lower rate than the perfect plate, and finally reaches a much lower point of discharge. On interrupting the current the plate which has not been discharged so far rapidly recovers a higher voltage than its neighbour, and therefore discharges into it.

This effect must also take place in the different parts of any one plate, and may be a cause for the formation of peroxide on the surface of a negative plate after a discharge, a phenomenon which I have never noticed, but which has been remarked by too many observers to be ignored.

The two outside negatives give more than their proportional amount of current on discharge, the current being actually less than on the other plates, the potential remains higher, and the discharge is therefore a little greater. This in turn affects the positives next to them, and these positives are usually the first to disintegrate in a carefully used cell. This fact was most noticeable in batteries used on the Eckington and Soldiers' Home Railway at Washington, where out of 20,000 positive plates there did not occur a single instance of buckling, and yet the outside positives always showed greater disintegration than the others.

The tendency of one part of a plate or one portion of

Digitized by Google

peroxide to discharge faster or slower than its neighbour is one of the reasons which induced us to adopt the equipotential methods of connecting up the several plates of the storage battery. It is to be noted that these phenomena occur to a serious extent only when the batteries are discharged below 1·95 volts of potential difference per cell.

The foregoing tables afford the most complete proof of the irregularity of the chemical actions which produce the E.M.F. of the battery. Now one plate is giving current, now another; and most remarkable of all, the different sides of the same plate exhibit differences of potential at their terminals which I can only attribute to differences of internal resistance, both in the electrolyte within the plates and in the porous active material itself.

The active material during charge and discharge is undergoing chemical change irregularly, not merely in the different plates, but in the different sides of the same plates, and as the active material is made up of large numbers of little pellets isolated from one another by the grid, the conclusion seems inevitable that one side of a given pellet is active to a different degree from the other side. It is not necessary to conceive that the E.M.F. generated on one side of a pellet is as different from the E.M.F. of the other side as would be indicated by the potential difference at the plate terminals. The more reasonable conception appears to be that the internal resistance of one side of a pellet is sometimes greater, sometimes less, than that of the other side, varying with the unequal chemical action. But I cannot escape the conclusion that there must be some real difference of potential, and consequently local action—not merely between the parts of the grid, but between opposite sides of the same pellet or paste. This would account for the fact observed by Ayrton that a working cell is always above the temperature of the air, even when its own temperature is falling in discharge.

In 1890, Prof. Ayrton in his most valuable contributions to storage battery literature independently noticed the fall of temperature in a discharging cell, and published a curve.

The explanation for at least a part of this phenomenon is simple. If, as we all know, the addition of sulphuric acid to water raises the temperature, it is natural to infer that the removal of the acid from the water will lower the temperature. The former occurs on charge, the latter on discharge.

(To be continued.)

THE GOVERNMENT AND THE NATIONAL TELEPHONE COMPANY.

The following correspondence between the Postmaster-General and Mr. Henniker Heaton, M.P., with reference to the bargain with the National Telephone Company has been published:

House of Commons, June 22, 1894.

Dear Mr. Arnold Morley,—I have to thank you for your reply to my question on the subject of the negotiations with the National Telephone Company, which is satisfactory so far as it goes. It still, however, leaves us quite in the dark as to the terms on which any full and final bargain can be effected.

May I therefore ask you to be good enough to state what, in the view of the Post Office, the Company is entitled under the existing license and agreement to claim consideration money for in the event (*a*) of an immediate purchase of all its rights and property by the State; and (*b*) in the event of a termination of the license by notice, or by effluxion of time, and of the Department desiring to acquire the company's wires, stock, and stations of exchange.

I am, dear Mr. Arnold Morley, yours faithfully,

J. Henniker Heaton.

P.S.—What I really desire to know is whether it is clearly stated in the license granted to the company that at the termination of the license they shall have no claim for goodwill or prospective profits. H. H.

The Right Hon. Arnold Morley, M.P., Postmaster-General.

Post Office, July 6, 1894.

Dear Mr. Henniker Heaton,—On the termination of the license in December, 1911, the right of the National Telephone Company to carry on telephone exchange business will cease and determine. All they will have to sell will be their plant, and even this the Government will be under no obligation to buy.

Believe me, yours very truly,

J. Henniker Heaton, Esq., M.P. Arnold Morley.

THE TENDERS FOR AYR.

We give below the list of tenders sent in for the supply of electric lighting plant for Ayr. The tenders, as mentioned in our "Business Notes," have been referred to the Electric Light Committee for determination.

Boiler-house Plant.	
James Neilson and Son	£1,762
John Cochrane	1,820
Yates and Thom	1,898
S. Z. de Ferranti	2,010

THE HISTORY OF WOODHOUSE AND RAWSON UNITED, LIMITED,

As Detailed in the Bankruptcy Court.

The enquiry into the affairs of this Company was resumed on Friday before Mr. Registrar Hood, at Bankruptcy Buildings, Carey-street, Lincoln's-inn.

Mr. Samuel Pope, Q.C., in reply to the Official Receiver, stated that he was not one of the original directors, but was appointed on August 5, 1889, along with Sir Rawson Rawson and Admiral Sir Leopold McClintock. He did not see and was not a party to any prospectus which had been issued previously to the date of his election on the Board. At the first meeting he attended he enquired whether proper investigation had been made into the properties and he was assured by Lord Aberdare, the chairman, that the most careful enquiries had been instituted, and that it was unnecessary for him to lose more time or incur further expense in looking into the matter, because the directors had exercised the utmost care in ascertaining the truth and correctness of the statements in the prospectus. He did not, therefore, enquire whether the profits for 1888 of the old company, as shown by the balance-sheet of June 30 of that year, had been realised or not. He was not aware that the balance-sheet was to some extent qualified by a report of the auditors. He had an interview with Sir John Coode, who informed witness that he was retiring because he was not satisfied with the amount of the applications for shares. Asked whether he understood that the business was to be mainly industrial or financial, witness said he believed it to be of a mixed character, and although the industrial portion was to be the "backbone" of the business, yet it was contemplated that a large amount of profit would be derived from promotion and financial transactions. He considered that the fact of the Company having a good industrial business would be the means of giving them greater facilities for floating electrical companies. The mistake made by the directors was in believing that the "boom" in electrical companies would be perpetual. If it had continued, the Company would not have been in its present position. He made no enquiry into the value of the assets acquired. He was not aware that certain patents which the new company was to acquire had lapsed long before 1889. In 1890 the patents were valued in the balance-sheet at £66,000. Witness did not personally take any steps to ascertain whether that was their real value or not, but he had no doubt that the directors as a body obtained the opinion of those best qualified to value the patents. So far as he was concerned he would never have passed the accounts as being correct if the figures were not *bonâ fide*. One source of profit to the Company was the manufacture and sale of incandescent lamps. Proceedings were instituted by the Edison and Swan Company to restrain the United Company from making the lamps, but a compromise was effected, each party paying their own costs. He was not aware that the industrial business showed a loss in 1890 until some long time afterwards. He was appointed chairman of the International Okonite Company, and a cheque for £30,000 was paid to the United Company on account of promotion money. The cheque was held over for a week at the request of the former.

The **Official Receiver**: Did you know that in the meantime the United Company, through Mr. F. L. Rawson and certain nominees, was applying for shares, and that a portion of these application moneys were used in supplying the funds to meet this cheque?

Witness said he did not know this, and could not say whether the applications were authorised by the Board. He always endeavoured to keep his interest as a director of the Okonite Company distinct from his interest in the United Company. If he had been aware that the industrial branch of the business was being carried on at a loss, he would not have been a party to the representation made to the shareholders that it was not. The balance-sheet of 1890 included a sum of £88,106 in respect of profits made in the financial business, out of total profits amounting to £109,000. According to the figures given to him by the Official Receiver there would have been a loss on the industrial branch of £13,000, but he did not agree with the Official Receiver's arithmetic, and thought the matter was more for an accountant than a lawyer. In 1892 he became aware that there was a great leak in the industrial branch of the business, and he immediately began to adopt special measures to stop it. He was present at the meeting of shareholders when it was decided to return the dividend guarantee fund of £75,000 to the liquidators of the old company, and he thought that transaction was beneficial to the new company. The liquidators, according to the balance-sheet, was entitled to a credit of £42,000, and the result of the negotiations was that a sum of £12,000 was deducted from the total amount due.

The **Official Receiver**: But that credit was subject to the realisation of the profits?

Witness said he could not understand the term "realised profits." It might be a very prudent thing for a partnership to decide not to divide their profits until they were received. The whole matter seemed to turn upon the question whether, at the date of the balance-sheet, the assets were fairly and reasonably valued. The shareholders were entitled to claim their share of the profits, and the directors could not refuse to credit them with those profits. So far as he was aware, the assets of the Company had always been fairly valued. He believed that the Okonite Company was now a prosperous company. The American shareholders of that company had intervened and turned witness and all the other English directors out. He would not have been connected with the company if he had not caught the "electric fever." The Epstein Company was formed on the last day of the financial year, and a profit of £35,145 was credited in respect of the promotion of that company, and he considered that the shares were very valuable, and would still be valuable if money could be found to work the patent, which was a very good one. At present there was no market for the shares, but they might yet be of value.

The **Official Receiver**: The shares have been sold for a shilling apiece.

Witness explained that this was merely part of an arrangement, and did not represent the actual value of the shares.

Mr. H. G. Rawson said the suggestion was that the shares were only worth a shilling.

The **Official Receiver** said he did not suggest that; he only wished to give the Company the benefit of the shilling.

Further examined, the **Witness** said that during 1890 the United Company appeared to have been continually borrowing money. It was said that the directors wished to avoid making a call on the shares, but he had no scruples himself on that point. In November, 1891, the directors decided that greater care ought to have been exercised by the managers of the Company, and they set to work to endeavour to stop the continuing loss on the industrial business. From accounts extracted by the secretary, it appeared that during 1892 a total loss had been made by the industrial branch of £15,000. Witness was not aware of that circumstance when he agreed to the declaration of a dividend. The auditor had never represented to him that it would not be advisable to declare a dividend for that year. There was an issue of a debenture stock prospectus in February, 1891, in which it was stated that the proposed stock would, after the existing stock had been paid off, become a first charge on the entire undertaking. He was one of the trustees for that issue, which had not become a first charge, as the previous one had not been paid off. It might have been desirable that the circular should have set out the nature of the security more clearly.

By **Mr. Pilling**: He was a shareholder in the old company. According to his ledger of bad debts his interest was £1,498, which he transferred to the new company, applying for a further £250 worth of shares in order that there might be no question as to the legality of his election to the directorate. He had never disposed of a single share. The shareholders of the old company were given the option of taking cash in lieu of shares in the new company, and he very much regretted that he had not exercised that option.

Mr. Pilling: Were you ever informed that your shares were very much enhanced in value, even to the extent of four times their original value?

Witness: Like Lord Aberdare, I can say that no such dream ever entered my imagination.

Questioned upon another point, **Witness** said that Mr. Pilling was entirely at liberty to make any suggestion he pleased, but whether he accepted it was quite another matter.

Mr. Pilling: Were you not conscious throughout from circumstances which came to your knowledge that the Company had paid too large a price for the business?

Witness: You are asking me to make an admission that I was consciously committing a fraud, and you cannot expect me to answer that in the affirmative.

Continuing, **Witness** said he supposed, as a shareholder, that he had received all the profits he was entitled to. He had always done his best to look after the interests of the shareholders.

Mr. Pilling said that the directors appeared to know very little about the affairs of the Company.

Mr. Registrar Hood said that no doubt Mr. Pope was well able to protect himself, but the Court could not listen to the speeches made by Mr. Pilling, who was only entitled to elicit facts.

In reply to Mr. M'Kay, **Mr. Pope** said that he had never repudiated any responsibility for the prospectus of 1889, nor had he admitted any with regard to the statements which it contained. The same answer applied to the subsequent prospectuses. He declined to volunteer an opinion upon matters now submitted to him, as he never gave an opinion without being paid for it. He did not pretend to be an expert upon any subject, but if a case were submitted to him for his opinion he would be pleased to consider it.

By **Mr. H. G. Rawson**: He had recently invested money in the Epstein shares.

At the close of his examination, **Mr. Pope** said he desired to state that he had one crumb of comfort in knowing that neither he nor his colleagues on the Board had put one single penny into their pockets at the expense of the shareholders.

Mr. Stutchbury, formerly secretary of the Company, was also examined as to certain accounts.

TUESDAY.

Mr. W. T. Stutchbury, formerly secretary and afterwards general manager of the Company, was recalled and further cross-examined on Tuesday by Mr. Jenkins. He stated that he had prepared an analysis of the various balance-sheets issued by the Company. It appeared that the account for the year 1891 showed a loss on the industrial business of £24,603. The accounts he prepared, showing the position of the Company as a whole, disclosed a loss of £15,000. Witness was of opinion that the stock was taken at a higher figure than it ought to have been. He was not an expert, but thought that something ought to have been written off on account of depreciation. He believed that on one or two occasions he represented his view of the matter to some of the directors.

Mr. Jenkins: Did they take any notice of your representations?

Witness said that generally his suggestions were politely

Digitized by Google

ignored. He had always been of opinion that the industrial business was a good one if it had been properly managed, and sufficient capital found to work it. He attributed the loss in this department to a great extent to the fact that there were too many departments, which were all, more or less, cutting the throats of the others; that there was no guiding hand over the whole concern; and that the works were scattered throughout the kingdom, necessitating a large expenditure for management. He also thought that sufficient care was not exercised in carrying on the business. At a meeting of the shareholders, held in 1892, witness made a speech in which he said that he believed the industrial business could be carried on at a profit, and that it only required more working capital to make the Company a success. He also said that his programme was "consolidation, retrenchment, and reform."

Mr. Jenkins: You considered that, although there might have been mismanagement in the past, the business was a good one, and could, with assistance, be developed into a paying concern?

Witness said that was so. He was informed by Mr. North, the former general manager, that in the earlier part of 1891 the industrial business was carried on at a loss. In spite of the loss the turnover of the business gradually increased. In April, 1892, witness was appointed general manager, and he immediately sent a circular round to the managers of the various branches expressing a desire that the businesses should be conducted in such a way as to work out at a profit. The shares and debentures in the International Okonite Company were included in the balance-sheet of 1891 at about £37,000. Witness had several conversations with the managing director as to the value of the shares. He did not pretend to be an expert so far as they were concerned, but he thought that as the Company had not realised any large amount for the shares or debentures they ought to have been taken at a lower value, and he still thought that would have been the wisest course to pursue. In the same balance-sheet, the Epstein shares were valued at £35,000. Witness did not think it was best to include the shares at par, and pass the amount as profit which had been realised, because they had no means of ascertaining the real value of the shares. The invention might have been, and might still be, a valuable one, but very few of the accumulators had been purchased. If he had been concerned in the matter he should have eliminated the £35,000, and included the amount expended upon the patent as a good debt. He knew nothing about the position of the Phœnix Trust, Limited, when the sum of £15,000 was included as the value of shares in that Company in 1891. He understood, however, that the profits of the trust were chiefly derived from floating companies in connection with the United Company.

By **Mr. Muir M'Kenzie**: He did not form any opinion as to the value of the patents at the time he joined the Company. He believed that the Company had a good future before it if it was properly managed. It seemed to him that the sum paid for the goodwill of the businesses (£97,000) was rather large. He understood that the old company was generally known as a promoting company.

Examined by Mr. F. L. Rawson, **Witness** said that if the stock and plant at the Kidsgrove branch had been revalued at £3,800 more than the Company gave for it the directors were perfectly justified in increasing the value to that amount. The Epstein shares were included at a discount of 10 per cent. at the suggestion of Mr. F. L. Rawson. Witness did not remember that Mr. Pope, Q.C., had said it was all "nonsense" allowing the discount, because they were worth their full face value. He had conversed with Sir Rawson Rawson as to the business of the Company, and he understood that gentleman was desirous of seeing the industrial branch extended. He did not think that the shareholders expected the profits on that business alone would pay the dividends of 15 per cent. Most electrical companies had made large losses, some to the extent of £15,000 or £20,000 a year. The competition experienced by the Company was so severe that the profits realised by it on each contract were so small as to be entirely swallowed up by the expenses. The Company had to keep up a large standing expenditure in the hope of getting more work in the following years. Witness endeavoured all he could to cut down the expenses.

By the **Registrar**: The competition was severe because the Company carried on dual businesses.

Witness further said that Mr. Rawson and the heads of departments had expended a considerable amount of labour and time in preparing the large catalogue, which time and labour was not charged for in the books. He should think that a sum of £2,000 would be sufficient remuneration for that work. The witness, shown a smaller catalogue prepared for Woodhouse and Rawson, Limited, thought that the charge for Mr. Rawson's time and the time of officials spent on its compilation and that charged directly in the books would be about £200.

Mr. Rawson: Would you be surprised to hear that it was worth £1,500?

Witness said that he would. He was not aware that the Press, in commenting upon the work, called it a history of electricity.

In reply to Mr. H. G. Rawson, **Witness** said that his relations with the chairman of the Company (Sir Rawson Rawson) were always cordial and confidential. That gentleman had given careful consideration to the views expressed by witness, and had on more than one occasion advocated them before the Board. Considering his age, witness considered that Sir Rawson Rawson was indefatigable in connection with the affairs of the Company. When the chairman told him that he expected the bulk of the profits would come from the financial branch, witness did not understand that he in any way discouraged the industrial side. He did not show Sir Rawson Rawson the trial balance-sheet of 1891, which disclosed a loss of £15,000. It did not appear to him to be reasonable to take into consideration the time spent upon a patent by an expert, because the invention might be valued at £20,000, and prove to be only worth 6d. With reference to the founders' shares, amounting to £25, which were subsequently included at £15,000 in a balance-sheet, witness said that before he consented to allow the latter sum to be included, he required Mr. F. L. Rawson to give him sufficient evidence that the shares were worth the amount. The evidence was produced and the shares were included in the amount stated.

By the **Registrar**: The reason for the severe competition and the small profits of the Company was that although their work was considered to be of the best kind, yet, owing to their financial business, their credit was not so good.

By **Mr. F. L. Rawson**: The directors were led by a former manager to believe that they had tided over all the difficulties of the industrial branch in 1891.

Sir Rawson W. Rawson, C.B., K.C.M.G., who was examined by the Official Receiver, stated that he was elected a director of the United Company on August 5, 1889, and attended the Board meeting held on the following day. He did not see, nor did he take any part in the preparation of, the prospectus before he joined the Board, as he was in the country at the time. He had not discussed the formation of the Company or the prospectus with his son.

The **Official Receiver**: Were you interested in any way in Woodhouse and Rawson, Limited, or any of the Woodhouse and Rawson companies?

Witness said that he was not. He was connected with another electrical company, but had nothing whatever to do with his son's companies. He was appointed a member of the works, finance, and contract committees, but there was not much work to do in connection with the last mentioned.

The **Official Receiver** then put to the witness a statement of Mr. Stutchbury's, which was to the effect that he had an interview with Sir Rawson Rawson upon the subject of the Company, when the latter stated that the industrial branch had been somewhat neglected, and that the directors looked to the financial business for a greater portion of the profits because they would probably bring out 10 companies where, in the past, they had only brought out one.

Witness said he did not think the statement was correct. He might have said that the directors hoped to obtain considerable profits from the financial business, but he had no recollection of making the other statements. He considered that the principal portion of the business consisted of the introduction of new electrical patents, and as the capital of the Company was so limited from the beginning, they were not in a position to work them, and it was therefore considered that it would be more profitable to the shareholders if the patents were transferred to other companies, from whom they might not only obtain an immediate sum, but also might become possessed of a future interest in the working of the patents.

The **Official Receiver**: Have you throughout parted with a single patent which you have acquired?

Witness said he could not remember whether they had done so or not.

The **Official Receiver**: Were not all these companies formed to purchase patents which you acquired after they had come into existence?

Witness said that he did not think this was the case. Further examined, he said he did not go minutely into the nature of any of the business acquired by the Company in order to ascertain whether they had been carried on at a profit or a loss. He could only remember that certain departments were represented as having made a profit. The gross income for the year ending June 30, 1890, was £109,000, a surplus of £61,085 being shown. He did not think that these profits ought to be considered exceptional, and they might have been repeated but for the Baring failure and the financial depression which followed. There was reason to believe that the statements in the prospectus would be realised. The Company confined itself to electrical matters, and the prospectus afforded ample scope for its operations. He contended that the statement in 1891 that the Company had a good reserve and favourable prospects was justified at the time.

The enquiry was then adjourned until the 20th inst.

LEGAL INTELLIGENCE.

A QUESTION OF TELEPHONE RENTAL

Judge Ellison has given judgment in the Sheffield County Court in the case where the National Telephone Company sued Messrs. Morris Bros., chemical manufacturers, Doncaster, whose works are at West Stockwith-on-the-Trent, to recover £50 rent due for a private wire. There was a counterclaim for £50 damages for alleged ineffective service of the telephone.

Mr. Ellison (instructed by Messrs. Webster and Styring) appeared for the telephone company, and Mr. Parkin (Messrs. Parkin and Co., Doncaster) represented Messrs. Morris Bros.

His **Honour** said the claim for rent was admitted, and therefore judgment would be entered for the amount. The counterclaim, with which he had only now to deal, was the damage alleged to have been suffered owing to the defective working and construction of the telephone. The damages were caused by delay in communicating between the works and the office of Messrs.

Digitized by Google

Morris, which had caused delay in executing orders for goods, put the defendants to additional expense for delivery, and had caused their customers to refuse payment, and loss of time in unsuccessful attempts to obtain telephonic communication. The contract entered into was that Messrs. Morris should pay £100 per annum in advance for a term of years for the use of a private telephone wire and three sets of instruments between the works at Doncaster and the works at West Stockwith. The conditions of the contract were that, subject to the performance by Messrs. Morris of the conditions laid down, the company would maintain the telephone in good working order. One of the conditions was the payment of rent in advance, and in point of fact it had always been in arrear. Another clause was, "In the event of the said wire or apparatus not being in good working order, the company shall repair and restore the same at its own expense, and with all possible despatch, but the company shall not be held responsible or liable to the lessee in damages or otherwise howsoever for any delay provided it uses every reasonable endeavour to restore the communication as speedily as possible." From the letters and evidence, it appeared that on numerous occasions the wire was out of order, caused by all kinds of accidents, such as the falling of branches of trees, shooting, rain, and the fumes from Messrs. Morris's works. In every case where a complaint was made to the telephone company it was at once acknowledged and attended to. He thought the telephone company had a right to complain of the way in which Messrs. Morris had brought the counterclaim. It was very well observed the other day that in nearly all cases a counterclaim was the result of an afterthought, and until this action was brought Messrs. Morris never thought of claiming. When the claim did come, it was in the most unfair way a claim could come against a company. How could a company explain everything that happened to one particular wire during three years? The counsel for the defence relied somewhat on a letter written by Mr. F. W. Carr, who stated, "We guarantee that the communication between your office and works will be absolutely satisfactory to you, and that any repairs, should there be any, will be attended to at once." There was nothing to show that this gentleman had authority to bind the shareholders, and there was no consideration for this, as was the case in the contract itself. On the whole, he thought the telephone company had performed their contract as well as such a contract could be performed, because the wire must be subject to sudden accidents of all kinds. They seemed to have remedied the cause of complaints as soon as they were mentioned, and in his opinion had taken a great deal of trouble in doing so. In more than one instance a clerk walked the whole length of the wire—22 miles—to find out where the fault was. That was extreme carefulness on the part of the company. He found a verdict for the company. His Honour gave costs on the higher scale.

COMPANIES' MEETINGS.

ELMORE'S PATENT COPPER DEPOSITING COMPANY.

As stated in our last issue, an extraordinary general meeting of Elmore's Patent Copper Depositing Company, Limited, was held on Thursday last week at the Cannon-street Hotel, Mr. Joseph Todhunter, J.P., presiding, for the purpose of receiving the resignation of the directors, and appointing new directors in their stead.

The **Chairman** first alluded to the failure of the Board in their endeavour to raise £10,000 in debentures last November. Arrangements were made with the Company's bankers at Leeds, through the intervention of Mr. William Elmore, for an overdraft, not to exceed £15,000. As a result of a consultation which the directors subsequently had with Mr. Elmore, that gentleman secured the services of three gentlemen who were willing to take over the direction of the Company's affairs, who were well acquainted with the details of the trade.

It was resolved that the resignation of the directors be accepted, and that Messrs. John Marshall (of Sunderland), John North (of Leeds), and Edward Reynolds (of Sheffield) be appointed in their stead.

BUSINESS NOTES.

Barrow.—St. Mary's Church is to be lighted by electricity.

Great Northern Telegraph Company.—For the month of June the receipts were £24,000.

Station-Lighting.—Electric light is being introduced into the joint railway station at Aberdeen.

Cape Town and Suburban Electric Lighting Company.—A dividend of 5 per cent. has been paid.

Western and Brazilian Telegraph Company.—The receipts for the week ended July 6 were £2,378.

Birmingham.—Electric lighting is to be introduced in the Town Hall on the occasion of the Royal reception.

Telegraph Stores.—The South Indian Railway Company invite by the 24th inst. tenders for telegraph and other stores.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 8th inst. amounted to £918.

Putney Electric Supply Company, Limited.—This Company has been registered with a capital of £1,000 in £2 shares.

Telegraph Construction and Maintenance Company.—This Company have declared an interim dividend of 12s. per share.

Wakefield.—The Wakefield Corporation Electric Light Order has been read a third time in the House of Commons and passed.

Commercial Electricity Supply Company, Limited.—This Company has been registered with a capital of £2,000 in £1 shares.

Great Western Electric Light and Power Company, Limited. This Company has been registered with a capital of £1,000 in £10 shares.

Torquay.—The Holloway Electricity Supply Company intend to apply for a provisional order for the electric lighting of Torquay.

Notting Hill Electric Lighting Company.—A half-yearly dividend at the rate of 6 per cent. per annum has been declared on the preference shares.

Anglo-American Cable.—The steamer "Britannia" has arrived at Hearts Content, Newfoundland, with 190 miles of cable for the new Anglo-American cable.

Coventry.—The Corporation has affixed the corporate seal to the contract with Mr. C. G. Hill for the erection of the buildings for the electric light station.

Appointment Vacant.—An assistant engineer is wanted by the Derby Corporation for the electric light station. Particulars are given in our advertising columns.

Tenders for Nelson.—Tenders are invited for the wiring and fittings in connection with the new technical school. Particulars are given in our advertising columns.

Aberdare.—The Committee of the House of Commons on Unopposed Bills have passed the Electric Lighting Provisional Orders (No. 4) Bill, relating to Aberdare.

St. Pancras.—The Vestry has accepted the tender of Mr. J. O. Richardson, of Albert Works, Peckham, for £7,117, for erecting the central-station buildings, King's-road.

Globe Telegraph and Trust Company.—This Company announce a dividend of 3s. per share on preference and 3s. 9d. on ordinary shares, carrying forward £500.

American and Parisian Massage Company, Limited.—This Company has been registered, with a capital of £10,000, for the carrying on of massage and medical electricity.

Tenders for Cheltenham.—The Corporation invite tenders for six 12-kilowatt transformers and ten 6-kilowatt transformers. Particulars will be found in our advertising columns.

City and South London Railway.—The receipts of the Company for the week ended July 8 were £879, against £1,069 for the corresponding week of 1893, or a decrease of £190.

Edison and Swan United, Limited.—The eleventh ordinary general meeting of the shareholders will be held at the Cannon-street Hotel, E.C., on Thursday, the 26th inst., at 11 a.m.

Dover.—The electric light company have given notice to the Town Council that they intend to lay mains in Camden-crescent, Wellesley-terrace, the Castle end of East Cliff, and round The Lord Warden.

Accident at Prescot.—Last week a boy named Reuben Rogers received a fatal shock at the works of the British Insulated Electric Wire Company at Prescot. A verdict of accidental death has been returned.

Payment of Coupons.—The Submarine Cables Trust give notice that on and after the 13th inst. the sum of £1. 5s., balance of the coupon due April 15, 1894, will be paid by Messrs. Glyn, Mills, and Co.

New Companies.—The capital of the new electrical companies registered during the first six months of the current year amounted to £1,969,500, as compared with £1,002,000 in the corresponding period of 1893.

Egyptian Tramways Construction Company, Limited.—This Company has been registered with a capital of £6,000, to acquire, develop, and deal in tramway and railway concessions in Egypt and elsewhere.

Lighting of Locks.—Messrs. J. P. Hall and Co., of Blackriding Ironworks, Werneth, Oldham, have completed electric light installations for the Manchester Ship Canal Company at the locks at Barton, Irlam, and Latchford.

Plymouth.—The Bill confirming a provisional order of the Board of Trade, conferring powers on the Corporation of Plymouth for the electric lighting of the borough, has been read a third time and passed by the House of Commons.

The Hastings Tenders.—Last week we gave a list of tenders received for the supply of electric light fittings for the Queen's Hotel, Hastings. We now learn that the tender of Messrs. B. Verity and Sons has been accepted.

Islington.—The Special Electric Lighting Committee of Islington Vestry have approved the designs of Mr. A. H. Tiltman, F.R.I.B.A., for an electric lighting station to be erected in Holloway-road, at an estimated cost of £17,542.

Lighting of the Embankment.—The London County Council have received the following tenders for the erection of a generating station in connection with the electric lighting of the Victoria-embankment: Foster and Dicksee, £5,562; and Kirk and Randall, £5,916.

Digitized by Google

Tenders for Bilston.—The Bilston Township Commissioners invite tenders for the electric lighting of their market house. Particulars are given in our advertising columns.

St. Luke's.—The St. Luke's Vestry have received notices from the engineer and manager of the County of London and Brush Provincial Electric Lighting Company, Limited, of the intention of the company to commence works in the parish.

Keighley.—At a meeting of the Keighley Town Council held on Tuesday, the town clerk was instructed to give a month's notice of a special meeting of the Council to authorise an application to the Board of Trade for electric lighting powers.

Yeadon.—The Board of Trade Provisional Order Bill empowering the Yeadon Local Board to supply electrical current by meter to consumers in Yeadon has passed through committee stage in the House of Commons. The Lords have already passed the Bill.

Portsmouth.—The Town Council propose to erect a refuse destructor at Eastney, and one of the Council suggested that it ought to be placed where it could be used in connection with the electric light station, but this proposition did not meet with support.

Hartlepool.—The Town Council have adopted a recommendation of the Lighting Committee empowering the Council to apply for a provisional order for electric lighting powers, but a special meeting of the committee will deal with the question before doing so.

Waterloo and City Railway Company.—Notice is given that the half-yearly general meeting of the shareholders of this Company will be held at the Waterloo Station, London, on August 9 for the transaction of the general business of the Company.

Lamp Agency.—According to an advertisement in one of the dailies, one of the largest factories of electric incandescent lamps seeks agents for England and the colonies. Applications are to be addressed to Incandescent, care of Mr. F. Algar, 11, Clement's-lane, E.C.

Helensburgh.—The Scottish House-to-House Electric Lighting Company having given notice to the Town Commissioners that they intended to apply for a provisional order for the electric lighting of Helensburgh, the Commissioners have resolved to oppose the application.

Tenders for Woking.—The Local Board invite by the 18th inst. tenders for the lighting of the Woking Station and Maybury Ward. A draft of the proposed contract can be inspected at the office of Mr. Robert Mossop, clerk, Bank-chambers, Woking. Tenders are to be sent to the clerk.

Eastern Extension, Australasia, and China Telegraph Company.—The interest on this Company's 4 per cent. mortgage debenture stock for the half-year ended 31st inst. will be paid by warrant on August 1. The stock register will be closed from 27th to 31st inst., both days inclusive.

Bowness.—The Local Board have received notice of the intention of the Troutbeck Company to apply to Parliament for powers enabling them to lay down plant for the supply of electric light within the Board's area. The clerk has been instructed to enquire into and report to the Board on the matter.

Stroud.—The Local Board of Health have received a letter from the captain of the Stroud Volunteer Fire Brigade (Mr. P. Ford), informing the Board that the brigade contemplated carrying out a system of electrical communication between the police station and the residences of their members at a cost of £31.

Direct United States Cable Company.—The directors recommend a final dividend of 2s. per share, free of income tax, making, with the interim dividends already paid, 2½ per cent. for the year ending June 30. The sum of £6,000 has been placed to the reserve fund account, and a balance of £1,032 has been carried forward.

Leeds Tramways.—The report to be drawn up on the system of haulage best adapted for the city, and to which we referred last week, has not yet been completed, the committee being still busy making enquiries. It is probable that some of the members will pay further visits to towns where different systems of haulage are in operation before the report is prepared. A trip to Douglas has been mentioned.

Morecambe.—The charges for the electric lighting service at Morecambe, as furnished by the Morecambe Electric Light and Power Company, Limited, have been increased as follows: for an 8-candle lamp, from 10s. to 12s. per annum; for a 16 candle lamp, from 20s. to 24s. per annum; and for a 32-candle lamp, from 40s. to 48s. per annum.

Barnet.—Messrs. Joel and Co. have written to the Local Board that they were about to apply during the session 1894-5 for a provisional order for the Barnet District Electric Supply Company to light the town of Barnet with electric light, and they forwarded the usual notices. The matter was referred to the Electric Lighting Committee.

Bradford.—The Bradford Bowling Green Club, Limited, have fitted up their bowling green with the electric light. The plant consists of a 4-h.p. gas-engine, and a Preece dynamo capable of lighting 60 incandescent lamps inside the club and four 1,000-c.p. arc lamps on the bowling green. Messrs. Andrews and Preece, of Bradford, laid down the plant.

Ambleside.—At a meeting of the Local Board, two letters were read, one from the Troutbeck Bridge Electric Works, and another from the Halloway Works, to give notice that they intend applying to the Board of Trade for a provisional order for electric lighting. It was decided to inform each company that the Local Board could not see their way to sanction it.

Chiswick.—The Works Committee of the Local Board have further considered the plans and elevations of the building at the pumping station for the electric lighting of the district, and instructions have been given to Messrs. Bourne and Grant to push on with the work as soon as possible.

Tenders for Watlington (Oxon.).—The Lighting Inspectors invite tenders for lighting streets, roads, and other places comprised in the parish either with oil or with gas, or any other illuminant. Tenders should be sent forthwith in a sealed letter, addressed to the Inspectors, Market-place, Watlington, of whom full particulars may be obtained.

Grange.—At a meeting of the Local Board a communication was read from the Windermere and District Electric Supply Company, Limited, giving the Board formal notice of its intention to apply to the Board of Trade for the supply of electricity for public and private purposes in this district. It was decided to refer the matter to the committee.

Shoreditch.—The Shoreditch Vestry have decided to memorialise the Board of Trade in favour of an extension of time within which to complete the electric lighting scheme. The appointment of an electrical engineer has been deferred to a future meeting. In connection with this matter it has been resolved to make application for sanction to borrow £12,300 for 60 years.

Water-Tube Boiler.—The Sanitary Works Committee of the Warrington Corporation invite tenders for the supply of a water-tube boiler. Specifications may be seen and further information obtained from Mr. James Deas, Longford Depôt, Warrington. Tenders to be sent to Mr. Deas by 23rd inst., addressed to the chairman of the Sanitary Works Committee.

The Clyde.—The Sub-Committee on Hydraulic Installation Building at Cessnock Dock recently approved of the plans as altered, and agreed that the buildings should be erected to these plans, at a probable cost of £11,600 for the whole buildings, which includes space for workshop, store, and electric lighting plant. The Clyde Navigation Trust have now approved this minute.

Scarborough.—The Scarborough Electric Supply Company, Limited, which has only been in operation about nine months, have already the equivalent of over 9,000 8-c.p. lamps connected to their mains. The directors, in order to meet further additions, have ordered from Messrs. C. A. Parsons and Co. another turbo-alternator to give 75 kilowatts, complete with condenser.

Tenders for Rugeley (Staffs.).—The Local Board desire by August 1 tenders for the lighting of the street lamps for the winter season, commencing September 1, 1894, and ending April 30, 1895. Particulars may be obtained of the chairman of the Lighting Committee, Local Board, Rugeley, to whom tenders should be sent. Mr. Robert Landor is the clerk to the Board.

Thames Ditton.—The members of the London Association of Foremen Engineers and Draughtsmen recently paid a visit to the works of Messrs. Willans and Robinson, at Thames Ditton, and were received by Mr. Mark Robinson and Captain Sankey. The members were split up into groups, each under the charge of a member of the firm's staff, and conducted round the various departments of the works.

Country-House Lighting.—Elveden Hall, in Suffolk, which has recently become the property of Lord Iveagh, is being fitted by its new owner with the electric light. About 500 incandescent lamps will be installed. The plant comprises two steam-engines and dynamos and accumulators. The work is being carried out by Messrs. Edmundsons, Limited, under the superintendence of Mr. A. A. C. Swinton, who, as consulting engineer, has arranged the installation.

Agency for Steam Accessories.—Messrs. Crosier, Mills, and Co., of Newcastle-on-Tyne and Sunderland, have been appointed agents on the north-east coast for Messrs. Holden and Brooke, Limited, of Salford, and are making a special display of injectors and other steam specialities at 58, Collingwood-street, Newcastle-on-Tyne, where they invite inspection of the Meldrum patent furnace, Richards's side planer, the Morse valve-reseating machine, and other labour and money saving devices.

Edmonton.—The Local Board have further considered the application of the Tottenham and Edmonton Electric Light and Power Company for sanction to apply to the Board of Trade for power to light part of Edmonton, from Tottenham boundary to Silver-street, with electric light and energy. The engineer and secretary of the company attended before the Board for the purpose of explaining its objects. The clerk was instructed to apply for the names of the gentlemen forming the company.

Tenders for Carshalton.—The Local Board invite by the 18th inst. tenders for the lighting of their district (consisting of the entire area of the parish of Carshalton) with gas, oil, or other illuminant, at per lamp, exclusive of the cost of columns, frames, and lanterns, for 12 months from 31st inst. Tenders, marked "Public Lighting," and addressed to the chairman of the Board, must be delivered at the Board Offices, High-street, by the date mentioned. Mr. Chas. P. Lovelock is the clerk to the Board.

Telegraphy to Singapore.—The chairman of the British North Borneo Company mentioned, at a meeting of the Company on Tuesday, that cable communication had been successfully established between Singapore and Labuan, and the directors had arranged with the Eastern Extension Telegraph Company, in consideration of this, to continue a land line across to Sandakan. They believed communication could be established for about £5,000, but, of course, this would only mean a rough track across country.

Paddington.—The Vestry have accepted the tender of Messrs. Dawson, Hammond, and Co., of John-street, Edgware-road, for

Digitized by Google

fixing private telephone wires (metallic circuit) and three sets of instruments connecting the Vestry Hall, Bridge House Wharf, and 11, 12, and 13, wharves. The Electric Lighting Committee of the Vestry have been instructed to ascertain from the Metropolitan Electric Supply and other companies if they are prepared to enter into an agreement to light the streets with electricity, and at what cost.

Birkenhead.—At a meeting of the Town Council, a letter was read from Mr. Robert Walker, Sandford-street, stating that the ratepayers of the borough were going to be called upon to provide a large sum of money for electric lighting. The cost of this could be largely avoided by obtaining from the Mersey Tunnel Company the 100,000 tons of water daily lost in being pumped into the Mersey. This force could easily be diverted into another course, and would thus drive the machinery and light up the whole town. The letter was allowed to lie on the table.

Lighting of the City.—The returns of the City of London Electric Lighting Company for the June quarter show that the revenue from the sale of current for public lighting amounted to £3,162, as compared with £2,838 for the corresponding period of last year, and the revenue in respect of private lighting was £7,153, as against £3,074. The total revenue is £10,315, being an increase of £4,401 over the same quarter of last year. The number of 8-c.p. lamps or their equivalent now connected is 99,140, as compared with 45,562 in June of last year.

National Telephone Company.—The directors have resolved to recommend the following dividend, less tax, for the eight months ending June 30 at the rate of 6 per cent. per annum on the amount paid up on the first and second preference shares, 5 per cent. per annum on the amount paid up on the third preference shares, and 5 per cent. per annum on the amount paid up on the ordinary shares, making, with the interim dividend already paid, 5 per cent. per annum for the 14 months ending with June. The balance left is about £67,000.

Eastbourne.—At a meeting of the Town Council, Councillor Martin asked the chairman of the Lighting Committee if he would consider the advisability of erecting an extra electric lamp opposite the top of Victoria-place, which he said was one of the darkest spots along the front. There were two or three small lamps that might be done away with, so that there would be no extra cost. A powerful electric light would enable visitors to inspect the beautiful carpet beds at night-time. Alderman Homewood, in reply, said the committee would, of course, gladly consider the suggestion.

Bromsgrove.—The Local Board on Wednesday received an application by letter from Messrs. Hemming and Co., electrical engineers, Birmingham, for the consent of the Board to the laying down electric lighting plant in Bromsgrove, so that they might apply to the Board of Trade for a license. Mr. Giles said he believed the applicants intended to lay down the greater part of their plant at Bromsgrove. As some members of the Board thought it was necessary that enquiry should be made before the matter was decided, he gave notice that he would bring it before the next meeting.

The City Polytechnic.—The foundation-stone of the third and last building of the City Polytechnic was laid on Monday by Mr. Charles Dorman. The City Polytechnic consists of the Birkbeck Institute, the City of London College, and the Northampton Institute, and a member of one institute enjoys the advantages of all three. The last named is being erected in St. John's-street-road, Clerkenwell. When completed there will be workshops for instruction in carpentry, turning, smith's work, clockmaking, plumbing, bookbinding, dressmaking, cooking, wood-carving, and the manufacture of electrical apparatus.

Provisional Orders.—The Committee of the House of Commons on Unopposed Bills have passed and ordered to be reported for third reading the Electric Lighting Provisional Orders (No. 3) Bill, confirming certain orders relating to Oswestry and Shrewsbury, and the Electric Lighting Provisional Orders (No. 4) Bill, confirming an order relating to Birmingham. These Bills have already passed the Upper House. The Bills passed by Mr. Mellor have included Bills to confirm provisional orders made by the Board of Trade under the Electric Lighting Acts, relating to Aberdeen, Chelmsford, Guildford, and elsewhere.

Brechin.—The clerk has reported to the Police Commissioners that on the instructions of the Lighting Committee he has written to the Northern Electric Light Supply Company, Aberdeen, who had intimated their intention to apply for a provisional order authorising the company to make an electric light installation in Brechin, putting several questions on the point. He also stated that he had received another notice from the House-to-House Electric Light Company, Glasgow, intimating their intention also to apply to the Board of Trade for a provisional order for supplying Brechin with electricity. The Commissioners decided to leave the matter in the hands of the Lighting Committee to consider and report.

Wolverhampton.—The Town Council have decided to renew the contract with the gas company for the supply of gas to the public lamps, etc., for 12 months, on the same terms as those contained in the previous contract, but subject to any variation rendered necessary by the laying down of the electric plant by the Corporation. Mr. Stevenson asked that the Council should enforce the fair-contract resolution passed by them in respect of the contractor who was erecting the electric lighting station in Commercial-road, and who, he said, had violated it by sub-letting a portion of the work. Alderman Jackson said that he knew nothing of the matter, and the town clerk stated that the Mayor would make enquiries and report upon it.

Monmouth.—There is some difficulty regarding the obtaining of a site for the drainage and electric lighting works. Messrs. Bramwell and Harris have written to the Town Council that the suggested buildings for the electric light station have all had to be rearranged. With regard to the provisional order, a letter was read from the Corporation's parliamentary agents in the matter (Messrs. Burchell and Co.) stating that the provisional order was read three times in the House of Commons and three times in the House of Lords, when it was referred back again in order that the compulsory and other areas should be certified. The borough surveyor was instructed to give the required certificate.

Sale of Plant.—Messrs. Wheatley Kirk, Price, and Goulty will sell by public auction, on Tuesday, Wednesday, and Thursday next, the contents of the works situate at St. Neots, Hunts, hitherto carried on by Mr. George Bower. The machinery includes lathes, drilling machines, planing machines, light and heavy plate-bending machines, punching and shearing machines, screwing, shaping, grinding, and other machines, cupolas, cranes, shafting, etc. The stock includes new horizontal steam-engines, exhausters, liquor pumps, new steel, bar iron, piping, etc. Catalogues may be obtained of Mr. Alfred Good, 57, Moorgate-street, London, E.C.; Mr. C. R. Wade-Gery, solicitor, St. Neots, Hunts; or of Messrs. Wheatley Kirk, Price, and Goulty, 49, Queen Victoria-street, E.C.

Hastings.—At a meeting of the Town Council, the Roads Committee reported that they were informed by the borough surveyor that the manager to the Hastings and St Leonards Electric Light Company, Limited, told him it would be very inconvenient to alter the site of the circuit-chamber proposed to be constructed under the public pavement opposite Messrs. Amoore and Son's premises at Robertson-street, the plan for which was, on the committee's recommendation, formally disapproved by the Council at the last monthly meeting. Under the circumstances, the committee now recommended that the plan for the chamber in the position indicated be approved, subject to the company undertaking not to remove the upper surface or cover of the chamber except between the hours of 10 p.m. and 9 a.m., unless in case of actual emergency. This was carried.

Church-Lighting.—The Castle-gate Congregational Church, Nottingham, was on Sunday evening experimentally lighted by electricity. The church was connected by electric cables with Messrs. Perry's factory in Stanford-street, and the installation was entrusted to Messrs. Danks and Co., Thurland-street, whose representative, Mr. Greenall, superintended the arrangements. The church was effectively illuminated by a large number of delicately-tinted lamps in various colours. A committee, specially appointed for the purpose, with the minister—the Rev. R. B. Brindley—at its head, carefully considered several modes of arranging the lamps. Mr. W. Longdon (Messrs. Danks's electrician) had charge of the installation. In the event of the scheme being adopted, it is proposed to make a permanent installation during the cleansing and redecoration of the church.

West African Telegraph Company.—The Company's revenue for the 12 months amounted to £61,847. 1s. 5d., against which £18,828. 19s. 1d. is charged for ordinary expenses, and £20,492. 5s. 11d. for expenditure relating to repairs to cables, etc. After providing £1,026. 6s. 1d. for income tax and £214. 8s. 3d. due to revaluation currency balances at stations, there remains a balance of £21,285. 2s. 1d., to which is added £2,410. 9s. 10d. brought forward from the preceding year, making a total balance of £23,695. 11s. 11d. From this balance there is deducted £12,495. 11s. 11d. for interest on debentures, and £11,200 for sinking fund. The total expenses attending repairs and renewals of cables, etc., amounted to £31,233. 17s. 6d., but the directors have decided to apply from the general reserve fund the sum of £10,741. 11s. 7d. to meet the deficit which would otherwise have appeared.

Halifax.—Upon the minutes of the Gasworks Committee coming up for confirmation at a meeting of the Town Council last week, Alderman Whitaker drew attention to the fact that they were introducing the electric light, and said that if the latter took well and became widely used the consumption of gas might decrease. He therefore counselled that in the interests of the ratepayers expenditure on capital account at the gasworks needed to be very carefully watched, and no more expenses ought to be decided upon. Applications for the electric light in Halifax continue to advance apace, and it is now pretty clear that considerably before the installation is completed the whole of the current will be taken up. The Masonic Hall Management Committee have decided to light their place throughout, and have entrusted the work to Messrs. Walter Emmott and Co., of Thomas-street, Halifax.

Ayr.—At a meeting of the Ayr Town Council on Monday night tenders for the introduction of the electric light, numbering in all 49, were submitted. The work was offered for in eight sections. The lowest offer amounted to £10,138, and the highest to £16,991. The lowest offer by one firm was £12 760—namely, Messrs. Siemens. Mr. James Smith, the convener of the Lighting Committee, stated that the offers had been submitted to Mr. Hammond, engineer for the work, and under his advice the committee had agreed to accept offers amounting provisionally to £11,834, which was somewhat under the original estimate. He pointed out that the aggregate of the lowest offers was £10,138. 0s. 6d. It was eventually agreed to remit to the Lighting Committee with powers to accept the offers referred to subject to certain adjustments, on the understanding that the aggregate would not exceed £12,000.

Brasyer v. Harness.—The action brought by Colonel Brasyer, C.B., against Mr. C. B. Harness and Dr. McCully, to recover money alleged to have been obtained by false pretences, and in

Digitized by Google

which the defendants counterclaimed for damages for malicious prosecution, was concluded on Tuesday before Mr. Justice Charles and a special jury in the Queen's Bench Division of the High Court. The jury said they could not agree whether Harness had been guilty of obtaining money by false representation, but they were agreed that Dr. McCully was not guilty; with regard to the charge of negligence and unskilful treatment, they were agreed that both defendants were not guilty. In reference to the cross-action the jury could not agree, and said they were evenly divided. Mr. Justice Charles gave judgment in favour of Dr. McCully in the action, with costs, and reserved the other questions for further consideration if desired.

Annual Excursion.—The employés of Messrs. Rashleigh Phipps and Co. held their annual excursion on Saturday last. Proceeding by an early train to Brighton, a pleasant morning was passed in and upon the water, after which the company, numbering the whole of the available staff of the firm, sat down to dinner, at which the usual toasts were proposed. In the afternoon the party proceeded in brakes and carriages to the village of Southwick, where the annual cricket match between carpenters and wiremen was played on the village green. The weather was all that could be desired, and the whole affair passed off with the most perfect success. We may mention that this firm is at the present time particularly busy with the electric lighting of a large number of private houses, principally in the London district, and notwithstanding the slackness usually prevailing at the present time in the electrical trade, the number of employés who attended the annual excursion exceeded last year's number by nearly 50 per cent.

Eastern Telegraph Company.—The report of the directors for the half-year ended March 31 last states that the revenue for the period amounted to £389,314, from which are deducted £102,218 for the ordinary expenses, and £49,660 for expenditure relating to repairs and renewals of cables, etc., during the half-year. There remains a balance of £233,813, to which is added £86,252 brought from the preceding half-year, making a total available balance of £320,066. From this balance there have been paid interest on debentures and debenture stock, dividend on preference shares, and an interim dividend of 2s. 6d. per share on the ordinary shares, leaving a balance of £222,001, from which £110,000 has been carried to general reserve fund. The directors now recommend the declaration of a final dividend for the year ended March 31, 1894, of 2s. 6d. per share and a bonus of 3s. per share, free of income tax, making a total distribution of 13s. per share, or 6½ per cent. for the year on the ordinary shares. The receipts for the month of June were £53,752, as against £62,564 for the corresponding period of 1893.

Bristol.—The Executive Committee for the restoration of Bristol Cathedral have generally agreed that the choir should be lighted by electricity and not by gas, but the precise method, whether by pendants or otherwise, has been postponed for future consideration. The Electrical Committee of the Bristol Town Council have been informed that the Local Government Board have sanctioned the borrowing of £24,650 additional capital for the purposes of the installation This sum will enable the committee to clear off existing liabilities and to make a few extensions. For example, the proposal to light the Cathedral and St. Mary Redcliff by electricity will be made possible by extending the mains in those directions. It is hoped, also, that sufficient money will be available for further extensions in order to promote private lighting in Clifton, whence the committee expect a profitable return in due course. Over £9,000 of the loan will be necessary for paying off the extra expense of the central depôt, which, on account of the unexpected piling and the additional accommodation provided, cost that amount more than was originally estimated.

Salisbury.—At a meeting of the Town Council the Town Clerk stated that he had received notice of the application of the Salisbury Electric Light and Supply Company, Limited, to the Board of Trade under the Electric Lighting Acts, 1882 and 1888, for a license. He had also received the following letter on the subject from Mr. Gramshaw: "1, Shorter's-court, London, July 4, 1894. Dear Sir,—I beg to enclose for the use of the Corporation six copies of the license as applied for to the Board of Trade. The kind way in which I have been met by the Council prompts me to ask for an early consideration of the same, as the company is anxious to proceed at once with its various arrangements.—Yours truly, W. H. Gramshaw." The Mayor remarked that whilst they warmly welcomed the electric light company to the city, there were certain interests which they as a Council had to safeguard. He did not know whether or not they might think it desirable that they should engage an electrical expert to advise them on any point which might arise affecting their interests. He had already received several applications for the appointment. After some discussion, it was resolved that the question should be referred to the General Purposes Committee, with instructions to appoint an expert at a cost not exceeding £50.

The Birkbeck Building Society.—The forty-third annual meeting of the Birkbeck Building Society was held last week at the offices, 29 and 30, Southampton-buildings, Chancery-lane. The report adopted states that the receipts during the year which ended March 31 last reached £10,014,003, making a total from the commencement of the society of more than 173 millions (£173,311,217). The deposits received were £9,102,698, and the subscriptions £218,366. The gross profits amounted to £220,833. The surplus funds have been augmented by £176,146, and now stand at £5,903,479, of which £1,732,248 is invested in consols and other securities guaranteed by the British Government, and the cash in the hands of the bankers is £449,814. A further sum of £25,000 has been added to the permanent guarantee fund, thus bringing up the amount to £175,000, and the balance £155,439, making together £330,439 in excess of the liabilities. The whole amount is invested in consols. The subscriptions and deposits withdrawable on demand amount to £6,053,681. The fourteenth triennial bonus on investing shares has been allotted, and the amount placed to the credit of all shares in existence at the close of the forty-third year is £52,237. The surplus funds (which are invested in convertible securities) are sufficient to pay the depositors 111¾ per cent. on the amount of their deposits.

Cardiff.—The Corporation Property and Markets Committee have decided to appoint the chairman and deputy-chairman of the committee to act with the chairman and deputy-chairman of the Lighting Committee, and the Mayor is to make arrangements for lighting the Town Hall, market, and other public buildings by electricity. The preparations for the lighting of Cardiff by electricity are progressing apace, and, as far as the street work is concerned, the pipes are all laid and most of the cables have been drawn in. Only two or three lamp pillars for street illumination remain to be erected, as their precise positions have not yet been decided upon. The building of the electric lighting station has been completed, and nearly the whole of the machinery has been delivered, and is now being fixed. The district to be lighted is that comprised in the compulsory area, and includes Queen-street, Castle-street, Duke-street, St. Mary-street, Custom House-street, Bute-street, from Custom House-street to the Hayes Bridge, the Hayes, Working-street, Wharton-street, and Church street. Mr. W. Harpur, the borough engineer, has stated that he thought everything would be ready for a start on September 1. They would supply private consumers at 6d. per Board of Trade unit, which was an exceedingly moderate price (being 2d. below the maximum allowed), and they hoped to get a large number of customers. The streets would be lit by 48 arc lamps. Private consumers would be supplied with the low-tension current for incandescent light and high tension for arc lights.

Rochdale.—A question was asked by Councillor Diggle at a meeting of the Town Council last week, whether the committee, in deciding to purchase two new boilers, had considered the advisability of the General Purposes Committee working with them with the view of making the new boilers generate power for supplying the electric light to the public buildings in the town? He moved as an amendment that boilers of 120lb. pressure be obtained, and that the committee be requested to use the additional power for lighting the public buildings of the Corporation by electricity. Councillor Turner, learning that the amendment was not seconded, said that he would move instead that the boilers obtained be boilers of the dimensions stated, but that they be made for 120lb. pressure, instead of 80lb. The time of day was passed for 80lb. pressure in boilers; the pressures generally worked were from 100lb. to 150lb. Whatever was the outcome of the electric lighting scheme, the Health Committee ought to provide themselves with high-pressure boilers. Councillor Diggle said he would second Councillor Turner's amendment. Councillor Turner's amendment, which was carried, was read by the deputy town clerk as follows: "That the minutes of the proceedings and resolutions of the Health Committee be approved with the exception of the minute referring to the purchase of two Lancashire boilers, and that such be referred back to the committee with the recommendation that any boilers purchased should be capable of working at 120lb. pressure at the least."

Belfast.—The new buildings to be erected from the designs of Messrs. Young and Mackenzie for the Young Men's Christian Association are to be lighted by electricity. Mr. Peach, of London, the architect for the new central lighting station in Chapel-lane, was in Belfast the other day, and visited the site and works. The adoption of the report of the Electric Committee, which recommended the payment of sundry accounts, was moved on Monday by Alderman Pirrie at a meeting of the Corporation, and was seconded by Councillor Andrews. Councillor Harrison asked if the chairman of the committee could give any information as to the time when they might expect to see the electric light in operation. Alderman Pirrie said that everything was going on remarkably well. The laying of the wires in the streets was proceeding in accordance with the contract, and was up to time, and the building of the central station was progressing very rapidly. He had no doubt but that by September he would be able to mention the date when the electric light would be on. Councillor Harrison said he would like to know if any information could be given as to the relative cost of the two systems of lighting. Some information should be given on this subject in order that people might know what they would have to pay for the electric light. Mr. Meyer said the committee had fixed 7d. per unit, subject to a discount as the price. Councillor Harrison said that did not answer his question. Mr. Meyer said electrical engineers were at variance as to the comparative cost, and, therefore, a layman could not give an answer. After further discussion the report was passed.

Whitehaven.—The chairman of the Town and Harbour Trust at a meeting last week referred to an application to the Local Government Board for increased borrowing powers on electric light account. He said they would remember that the original application to the Local Government Board for powers to carry out the electric lighting order was for £14,000. At the enquiry that was held, Dr. Hopkinson presented a supplementary estimate, which involved a large increase of the works, more especially with regard to the mains; and his estimate for the extra work was £7,000. An application was made at the enquiry that the amount of loan to be sanctioned should be £21,000 instead of £14,000. However, the Local Government Board gave their sanction to the £14,000 only, as required by Dr. Hopkinson's original estimate.

Digitized by Google

The work that was included in Dr. Hopkinson's original estimate had all been carried out, at an expense of £12,294. 14s., which was some £1,700 under the original estimate of £14,000. But in carrying out this work from time to time there had been certain additional works sanctioned by this Board, especially the extension of the mains to Arrowthwaite, and the extension to Hensingham-road. These two outlying places were not included in Dr. Hopkinson's original scheme. Then there had been also a great number of lamps added at places not previously lighted by gas, where it was found highly desirable lamps should be placed; and there had been altogether 43 lamps more erected for public lighting than was specified in the original contract. The result was that the extras over and above the original contract amounted to £3,199. 19s. 2d., and the proposal of the Electric Lighting Committee was that this Board should ask the Local Government Board now to sanction the borrowing of £4,000. This motion was adopted.

Taunton.—Since the works of the electric light company have been acquired by the Town Council a number of important alterations and extensions have been made with a special view to increased efficiency and economy. The alterations have been carried out on the advice of Dr. Fleming, the electrical adviser of the Council. Iron guards have been provided to protect the belting and other exposed dangerous parts of the machinery. The boiler plant, which was previous incomplete, has been supplemented by an "Economic" boiler, made by Messrs. Davey, Paxman, and Co., and capable of evaporating 4,400lb. of water per hour, or about 105 nominal horse-power. The old cast-iron steam-pipes have been taken down and a new system of steel drums and wrought-iron pipes fixed. The additions to the engine and dynamo plant consist of a 50-h.p. Bumsted and Chandler engine, driving a 30-unit Thomson-Houston alternator at a speed of 1,500 revolutions per minute, by means of belt gearing. The engine runs at 380 revolutions per minute. The new underground conductors are laid on the "transformer sub-station" system, where the high-tension current is led direct to large transformers in some convenient building, close to the area of supply, from whence low-tension cables distribute energy to consumers on the "three-wire system." No. 1 sub-station, which is now completed, is under the Municipal Buildings. A high-tension, concentric armoured cable, made by the Fowler-Waring Company, composed of 19 strands of No. 18 S.W.G. wire, runs from the works to the sub-station. Here it is led by means of suitable switching gear to two 30-kilowatt transformers, which supply current at 200 volts pressure to three feeders which convey it to the consumers' houses. Mains are laid around the Parade, and along sections of High-street, East-street, and North-street, making a 220 yards radius from the Municipal Buildings. The Town Council on Friday considered a favourable report by Dr. Fleming on the electric lighting works recently acquired by the Town Council. The lights in use last October numbered 1,055 of 16 c.p., whereas now it is 1,674.

Montrose.—The question of introducing the electric light into the town was again under consideration at a meeting of the Police Commission on Tuesday, when Mr. Whiteman, convener of the Lighting Committee, moved that the Commissioners apply to the Board of Trade for a provisional order. He thought that such an order should be asked for. Seeing that two companies were already in the field proposing to supply the light, it stood to reason that those companies had good prospects of deriving a profit from their speculation, or else they would not have applied for permission. When an order had been obtained they could then proceed to get all the information necessary as to the probable expense, and they might decide to arrange with some company to supply the lighting, when the fact that they had obtained such an order would enable them to make better terms with competing companies. The Chairman, in seconding Mr. Whiteman's motion, stated that in terms of the Act they could not settle anything at that day's meeting, seeing that one clause of the Act specially provided that no application for a license could be made by any local authority unless a resolution was first passed at a special meeting of the local authority, of which at least a month's notice had been given. His special reason, however, for seconding Mr. Whiteman's motion was that he thought it was very undesirable in the public interests that they should be thrown into the hands of any private company. Mr. Strachan moved that, instead of applying for an order for themselves, they should entertain the application of the House-to-House Electric Supply Company. He was satisfied that the carrying out of an installation could not be accomplished on more favourable terms than those offered by that company. Mr. Strachan failed to find a seconder to his motion. On the suggestion of the Provost, Mr. Whiteman agreed to alter his motion to the effect that as the Board did not consider it expedient to accept the offer of any private company, a special meeting of the Commission should be called for the purpose of taking into consideration the present state of affairs, and the expediency of applying for an order for themselves. After further discussion, this motion was adopted.

Walsall.—The Corporation of Walsall having applied to the Local Government Board for the necessary sanction to the borrowing of £22,000 for the purpose of electric lighting, an enquiry took place at the Town Council Chamber on Friday morning last week before General Henry Darley Crozier, R.E., inspector. There were present the Mayor (Councillor T. P. Brownhill, J.P.), Councillor Marshall, Councillor Noake, Mr. Tindall (gas engineer), Mr. R. H. Middleton (borough surveyor), Councillor William Smith, Alderman Lindop, Alderman Newman, the town clerk (Mr. Cooper). The Town Clerk (Mr. J. R. Cooper) stated that the population of Walsall stood at 75,000 according to the most recent estimate, and was rapidly going up. The estimated value was £151,210. Regarding the scheme, the area of supply was the whole of the borough. The borough was of a very scattered character, the total length being about seven miles, and an average breadth of about three miles. Over 60 miles of public highways were possessed. There had been no application by any person or company within the area to provide electric lighting. The attention of the Council had been engaged some time on the subject, and Mr. Frederick Brown was called in by them as adviser. It was upon his advice, and after having inspected some of the best electric lighting stations in London and the provincial towns that they concluded that the high-pressure system was best adapted to the town of Walsall. Mr. Cooper, continuing, said they wanted a system capable of meeting the full requirements. Lying to the north of the borough there was practically another town containing about 12,000 people; he referred to Bloxwich. In all probability there would be a demand made upon them to supply that part of the borough. The scheme had been submitted to and approved by the Board of Trade. As to the site of the works, the Corporation proposed to appropriate part of the site of the Wolverhampton-street gasworks. Up to the present time the town had been supplied with two gasworks, both belonging to the Corporation—one at Wolverhampton-street, which was an old works established some 40 or 60 years ago, and the other a modern works at The Pleck about 20 years old. This year the Corporation were abandoning the Wolverhampton-street works for the purpose of the manufacture of gas, but would still use them as a storing station. It was proposed to appropriate 2,370 square yards as a site for the station. It abutted on the canal and was conveniently situated for the purposes of a generating station. Mr. Brown then rose and explained the working of the scheme in some detail.

Gas and Electricity at Blackpool.—In our issues of June 22 and 29, we gave an abstract of the paper read by Mr. William Chew before the Incorporated Gas Institute on the "Gas and Electricity Supply of Blackpool." Some correspondence on the subject has since been published in a Blackpool paper, and in this connection Mr. J. Hesketh, the borough electrical engineer, replies as follow: "My natural antipathy to appearing in a public controversy has been my excuse for letting previous criticism connected with the electricity works pass unchallenged. But when from the utterances of the assistant gas engineer are drawn distorted conclusions acting against this department, I must beg your indulgence if I intrude myself. Mr. Chew's paper contains much interesting information. That with reference to the gas department he has every reason to be confidently proud upon. That with reference to the electrical department, I think, would have been better held over until at least a year's working had given more reliable averages than can be obtained from the midsummer results. A word as to the results up to March 25, 1894. The charges in the totals given by Mr. Chew included all charges, such as preliminary trials of machinery, tests, etc. This point should not be lost sight of. It makes a large proportion of the total cost. By far the most important point, however, is the one which is raised: that at an output of 4,000 units a week, can we hope to produce electricity at a paying cost? Mr. Chew's deductions are admirable so far as they go. The only regret I feel is that he has not investigated the possibility of this output being reached and placed it before your readers. The unfortunate impression is given that it is Utopian to expect this demand. Let us see whether or no we can hope for it. We have installed in Blackpool at the present moment over 2,500 16-c.p. lamps. These absorb 160 units every hour they are used. Mr. Chew's experience enables him to give four hours as the average time an ordinary lamp is used daily. Then 160 units by four hours per day gives 3,840 units per week, neglecting Sunday. But this does not include the arc lamp consumption, which is at the rate of 40 units per hour. As arc lamps in Blackpool are used only till midnight, we can only take an annual consumption of, say, 1,500 hours per lamp—this is a low estimate. Therefore, 60,000 units are to be used annually in this service alone, or, say for simplicity's sake, 1,000 per week. That with the incandescent lighting, brings up the output average to 4,840 units weekly. I am aware that this glaring conflict of facts arrived at by legitimate deduction with those deduced from Mr. Chew's appears at first sight rather strange, and I may therefore be allowed to point out where I imagine the error has crept in. Mr. Chew says 'the plant has reached its maximum capacity,' and one argues therefrom to a rather false conclusion. True, the plant has reached its maximum capacity at any one moment. But it requires no demonstration on my part to show that the maximum demand being reached for a brief moment or two at the turn of a summer night, is no measure whatever of the earning capacity of that plant when the nights lengthen. It is the omission of this 'time factor' (if I may be permitted to use an almost technical term) which falsified the almost necessary deductions from Mr. Chew's paper. I would emphasise that these calculations are on our present connections. We have in view many more. I may perhaps now be allowed to extend the point raised by the gas engineer, and draw attention to the output on which electricity works have paid and will pay. Newcastle in 1891 paid on an average delivery to consumers of slightly under 5,000 units weekly, in 1892 of 6,000, and 1893 of 6,500 (roughly). Dublin has an average of 6,500 weekly, Brighton of 5,000, and Bradford of 9,000. These are not large figures, and if I might venture a pertinent question, I would ask what gasworks on an output of the equivalent to 4,000 units weekly—that is, an output of 400,000 cubic feet of gas—would venture to sell at less than 5s. per thousand? This puts the cases on the same level. The gasworks

Digitized by Google

produced during the year ending March 25, 1894, 242 million cubic feet, or an average of slightly over 4,650,000 cubic feet weekly. This is equal to 46,500 units of electricity, or rather more than 10 times the amount on which we are asked to show profits approaching those of the gasworks. With a demand approaching 5,000 units weekly these works will pay, and until it is seen whether the average weekly output will reach this amount I think judgment should be deferred. As the demand increases, and the nights lengthen, the cost will be reduced, and I trust that then even the most anxious to cavil will have no opportunity. I am sorry that there still seems some doubt as to the system on which we are working. I think that an extract from Mr. Chew's paper might have given the idea he wished to convey, and at the same time strengthened the public knowledge if it had been worded somewhat thus: 'One result of the rapid development of these new electricity works has been that the expensive system of separate transformers in separate houses has, in view of the large demand at the end of six months, been advanced to that of distribution from half-a-dozen transformers placed in the streets.' This will naturally in the development of the business have to be still further extended to several more, as the demand increases, forming what are known to gas engineers as town governor-houses. I am not anxious to question the reasonableness of expecting any works during their first year's working to do more than strengthen that which they hold. I trust only that in endeavouring to vindicate the claims we have laid to public confidence I do not betray that of our Corporation in giving figures which to the present date at least can only be experimental, and until the time when they can be officially presented to the ratepayers are only known under the head of "Private and Confidential.'"

PROVISIONAL PATENTS, 1894.

JULY 2.

12767. **Improvements relating to electric incandescent lamps.** William Henry Willatt, 22, Jalland-street, Holderness-road, Hull.

12817. **Improvements in electric incandescent lamps.** Albert Zobel and Fritz Buchmüller, 18, Buckingham-street, Strand, London.

JULY 3.

12861. **New or improved electrical fishing apparatus.** Edward Poppowitsch and Herman Wüstenfeld, 34, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12870. **Improvements in electric switches.** Claud Hamilton, 70, Wellington-street, Glasgow.

12875. **Improved alternating-current meter and method of measuring alternating currents.** John Forrest Kelly and William Stanley, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12877. **Improvements relating to the operation and control of steam machinery or other mechanism by means of electricity, and in apparatus therefor.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (John Dunlap Williamson, jun., United States.) (Complete specification.)

JULY 4.

12928. **Improvements in or in connection with the commutator brushes of dynamos.** John Alfred Edmondson, 2, East-parade, Leeds.

12946. **Improvements in arc electric lamps.** Samuel Sealy-Allin and William Henry Wood, 52, Woodstock-road, Bedford Park, London.

12965. **An improved contrivance for automatically switching on and off electric currents suitable for many purposes.** George Bett Blanchard and Arthur Ballance, 8, Quality-court, Chancery-lane, London.

12972. **Improvements in electric arc lamps and current regulators therefor.** Stefan Doubrava and Josef Donát, 6, Bank-street, Manchester. (Complete specification.)

12982. **Improvements in electric arc lamps.** James Brockie, 28, Southampton-buildings, Chancery-lane, London.

12991. **An automatic cut-out for electrical heating and cooking appliances.** John Alexander Macmeikan, 97, Newgate-street, London.

12993. **Improvements in the electrolytic separation of gold from ores.** Alexander Cruickshank, 40, Chancery-lane, London.

JULY 5.

13018. **Improvements in electrical firing keys.** Herbert Vivian Keeson, 40, Loudoun-road, St. John's Wood, London.

13042. **An improved contrivance for automatically switching on and off electric currents, also suitable for many purposes.** George Bett Blanchard and Arthur Ballance, 8, Quality-court, Chancery-lane, London.

13063. **Indicating lamp failures in electric lighting circuits and apparatus therefor.** George John Tom Jelley Parfitt, 4, South-street, Finsbury, London.

JULY 6.

13078. **An electric resistance switch improvement for lowering incandescent lamps.** Edward Russell Cummins, 38, Gracechurch-street, London.

13082. **A method of and apparatus for fixing or erecting telephonic, telegraphic, or other wires.** Charles Shore, 2, Old Market-chambers, Yorkshire-street, Rochdale.

13115. **Improvements in telephonic transmitters.** Guillaume Arnaud Nussbaum, 29, Ludgate-hill, London.

13136. **Improvements in or appertaining to submarine telegraph and like cables.** Herbert Arnaud Taylor and Joseph Arthur Lovel Dearlove, 124, Chancery-lane, London.

13148. **Improvements in electrical measuring and recording instruments.** Haydn Thies Harrison, 46, Lincoln's-inn-fields, London.

13157. **Improvements in means for insulating electric cables.** Georg Eduard Heyl, 37, Chancery-lane, London.

13158. **Improvements in electric fuses.** Georg Eduard Heyl, 37, Chancery-lane, London.

13160. **Improvements in the manufacture of electric cables.** George Gatton Melhuish Hardingham, 191, Fleet-street, London. (The firm of Felten and Guilleaume, Germany.)

JULY 7.

13182. **Improvements in electric light ceiling roses.** Charles Richardson and Edward Herbert, Cornbrook Park-road, Manchester.

13208. **Improvements in field magnets for continuous-current dynamos.** William Henry Allen, Richard William Allen, and Charles Cæsar Hawkins, York-street Works, Lambeth, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

16028. **Compensating variations of lead at electrical stations.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

16175. **Electrical fittings.** Lundberg.

1894.

5796. **Underground conduit systems for electric railways.** Petersen.

6046. **Effecting electrolysis of saline solutions.** L. A. P. and H. E. A. Lienard.

7645. **Underground conduits for electric railways.** Brand and Franklyn.

7879. **Reflectors for electric arc lamps.** Coerper.

8273. **Shade tilt for electric light pendants.** Claremont.

NOTES.

Electric Lighting in Berlin.—The Berlin Electricity Works intend to extend their mains.

Matabeleland.—Telegraphic communication between the Cape and Buluwayo has been opened.

Telegraphy in China.—It is stated that Pekin will shortly be connected direct with St. Petersburg.

Blackpool Electric Tramway.—The electric cars on this line have, we are glad to say, now been again set in operation.

Flensburg.—The new town theatre is to be supplied with an electric light installation by the General Electricity Company of Berlin.

Electric Lighting at Frankfort-on-the-Maine.—A large new church, the Peterskirche, is being built here, and will be lighted electrically.

Electric Lighting at Biarritz.—The central station is expected to be completed in September. The Grand Hotel is putting up an independent installation.

Society of Chemical Industry.—This society held its annual general meeting in Edinburgh on Wednesday, Mr. Stanford, the president, occupying the chair.

Atmospheric Electricity.—A discharge of atmospheric electricity has destroyed the telephonic system in the Spanish Cortes and frightened some of the members.

Treguier.—In the electric lighting of this small town, situated on the Cotes-du-Nord, a Davey-Paxman semi-fixed engine and two Rechniewski dynamos are to be laid down.

Aix.—The inhabitants of Aix-en-Provence are urging the Municipal Council to establish electricity works so as to remove the burden imposed upon them by the local gas company.

Electric Lighting at Hengersberg.—An electric light installation has been started in this Bavarian town by Mr. Steininger in his mills. There are two dynamos driven by means of turbines.

Marseilles.—The local gas company, which also supplies electric light, has made experiments in street-lighting with arc lamps at the request of the Town Council, and now an extension is being made.

Freiberg (Saxony).—An industrial exhibition has been opened here, and will be kept open till the middle of August. The various buildings are connected by an electric mining tramway.

Electric Lighting at Weissenfels.—The Municipality have decided to build a central electric light station. The work will be carried out by the German Electricity Works of Aix-la-Chapelle.

Electricity at Zittau.—The Municipality propose to erect a central electricity station here. Circulars have been issued in order to ascertain the probable demand for current for light and power purposes.

The Latest from the States.—The American papers state that an electric light is to be placed in the Fire Island lighthouse, off New York, the candle-power of which is estimated to be 450,000,000 candles.

Traction in Paris.—It appears that the promoters of electric traction in Paris have not been very successful, since the Compagnie Générale des Omnibus is laying down the Mekarski compressed-air system.

Traction in Switzerland.—The construction of the electric tramway at Champel-Petit-Saeonnex, Geneva, which is being carried out for the Compagnie des Tramways Suisses, is being rapidly pushed forward.

Thurgau.—A movement is on foot in Switzerland for the establishment of telephonic communication between Kreuzlingen and Frauenfeld, with a further extension between Kreuzlingen, Schaffhausen, and Basle.

Electric Lighting at Gebweiler.—A syndicate has been formed to introduce the electric light at Gebweiler. It is proposed to use the water power of the Lauch for this purpose, a head of about 1,300ft. being available.

Poitiers.—Extensions which are being made in the electric lighting of this town include a Weyher and Richemond steam-engine, and a Brown alternator giving 2,400 volts at a frequency of 80 periods per second.

Morez.—This industrial town in the watch manufacturing district of Jura is to be lighted by electricity. Power is to be obtained from the Grandvaux lake, so as to supply 6,000 lamps and electric motors of 300 h.p.

Messrs. Naglo Bros., Berlin.—This firm of manufacturers of telegraph and telephone plant and electric machinery have erected new works at Treptow, near Berlin. All the machinery is run by means of electromotors.

Electric Lighting at Wynau.—Dr. Budde, of the firm of Messrs. Siemens and Halske, has been visiting Wynau, in Switzerland, in connection with the erection of a central electric light station there. Work is to be commenced shortly.

Telegraph Subsidy.—The *Indian Engineer* states that the European telegraph companies which work together with the Chinese Telegraph Administration, derive a yearly subsidy from Russia in connection with the Siberian lines.

Personal.—Dr. Kaiser, of Hanover, has been called upon to succeed Prof. Henri Hertz in the chair of instruction in physics at the Bonor University. Prof. F. Kohlrausch, of Strassburg, has gone to Berlin as the successor to the late Prof. Kundt.

Pressburg Electric Traction.—The Ministry of Commerce has approved of the agreement of the Pressburg Municipality with Messrs. Werner, Ganz, and Co. for the construction of an electric tramway, but has laid down as a condition that the plant must be made in Hungary.

Incandescent Lamp Action.—The appeal of M. Augé against the judgment delivered in favour of the Compagnie des Lampes Incandescentes Edison-Swan, who had proceeded against him for infringement of lamp patents, has been dismissed by the Paris Court of Appeal.

Association of Municipal Engineers.—We understand that a large party of the Incorporated Association of Municipal and County Engineers will pay a visit to Belgium next month, and that the electric tramway and central station in Brussels and the Antwerp Exhibition will be inspected.

French Electro-Metallurgical Companies.—According to a French contemporary, it is stated that an agreement has been come to between the Compagnie Française des Métaux and the French Elmore Company whereby vexatious competition between the two concerns will be avoided.

Electrical Workmen.—It is noteworthy that the Chambre Syndicale des Ouvriers Electriciens (Chamber of Electrical Workmen), of 13, Rue Aumaire, Paris, has established a sitting every evening from 8.30 to 10 p.m., where managers of electricity works can find men capable of doing all kinds of work.

Electric Traction in Austria.—The Austrian Minister of Commerce has authorised the construction of the following local railways, on which possibly electric

Digitized by Google

traction will be adopted: between Stag and Golling, between Gosaumühle and Gohausen, between Obertraun and Lahn, and between Golling and Bluntau.

Amsterdam.—The new town theatre is being fitted with the electric light by the Hamburg agency of the General Electricity Company of Berlin. The installation will comprise 2,000 incandescent lamps, 12 arc lamps, and four electromotors. There are two horizontal compound engines each of 60 h.p. It is also proposed to light the town hall by electricity.

Electric Lighting at Borkum.—The Dorf and Strand Hotels, both of which belong to the same proprietors, and which are about three-quarters of a mile apart, are being electrically lighted by the Bremen agents of Messrs. Schuckert and Co. The generating station is close to the latter of the two hotels, and the three-wire system is being employed.

A Telephone Action.—The Liège Court of Appeal has given judgment in the action brought against the Société des Téléphones by the Compagnie Continentale Edison. In the first instance the Namur tribunal nonsuited the Edison Company. The Liège court has, however, nullified this judgment, and concluded that if the use of the induction coil has become public property, the plate in the Blake apparatus constitutes an improvement, and cannot be employed in the Edison apparatus without a previous understanding with the company owning the latter.

Obituary.—The death is announced of M. M. P. Lemonnier, one of the founders of our French contemporary *L'Industrie Electrique*. The deceased, who was formerly connected with the firm of Sautter-Lemonnier, which on his retirement became Sautter, Harlé, and Co., was president of the Société Internationale des Electriciens in 1888. We also have to record the decease of M. Edmond Julien, whose type of accumulator is well known; of M. Pierre Houry, wire and cable maker; and of Prof. A. Kundt, who succeeded Prof. Helmholtz at the Berlin Physical Institute.

Illuminating Power of Search-Lights.—Mr. F. Nerz treats in the *Elektrotechnische Zeitschrift* of July 5 of the illuminating power of search-lights, with special reference to the large projectors made by the Schuckert Company. The author examines various criticisms made by Prof. Silvanus P. Thompson, Mr. Carl Hering, and M. Blondel, and concludes by stating that the efforts made by that company in the direction of getting introduced an accurate system of determining the lighting powers of search-lights should receive the attention and support of all interested in this branch.

Telephony in Nottingham.—The commencement of operations in the building of the new post office in Queen-street has rendered it necessary for the National Telephone Company to remove their wires, which run directly over the site. Pending their removal and for future service a cable is being laid underground from the central office to Ilkeston-road, where it will be connected with a distributing pole, which will supply the wants of the subscribers of the neighbourhood. It is expected that the work, which is being carried out under the superintendence of Mr. R. C. Bennett, district manager, will be completed in October.

Appointment of City Inspector.—The City Commission of Sewers on Tuesday elected an electrical inspector at a salary of £250 per annum. There were 88 candidates, and this number was reduced to three, whose names were Mr. T. A. B. Carver, 26; Mr. O. C. Gerhardi, jun., 25; and Mr. A. A. Voysey, 30. Each of these candidates had been approved by Mr. W. H. Preece, the electrical adviser of the Commission. Mr. Voysey, who gained 32 votes against 22 by Mr. Carver, was elected. Mr. Voysey, in thanking the Court, promised he would serve the Commission faithfully and well. A grant of 10 guineas each was made to the two unsuccessful applicants.

Production of Chromium.—It is stated that M. Moissan has succeeded with his electrical furnace in preparing for the first time chromium in a pure state. On Monday, before the Academy of Sciences, he was able to show, according to a Paris correspondent, the relatively large quantity of 40lb. of this rare metal. It is entirely free from carbon, does not scratch glass, can be filed easily, and is whiter than iron. It is untarnishable, and acids have no action on it. M. Moissan purifies it in his electric furnace in presence of a double oxide of calcium and chromium. M. Moissan exhibited to the Academy new alloys of chromium with aluminium and copper which are tough, malleable, and untarnishable.

Large Armature Stars.—A pair of probably the largest armature stars or carriers in the world has recently been made for the Siemens and Halske Electric Company, of America, who will put them down for street railway service at Toronto, Ontario. The machines when completed will weigh about 60 tons each, and have a nominal capacity of 1,200 kilowatts, or 1,600 e.h.p. each, under 50 volts pressure, and will be over-compounded for 12 per cent. drop in the lines. They are to be directly connected to a pair of horizontal cross compound condensing engines making 80 turns per minute. The armature stars are 13ft. in diameter, and weigh something over 10 tons each. The brush carriers will be about 14ft. 6in. in diameter.

Telegraphy with the Far East.—As we mentioned in a note in our issue of 6th inst., the commemoration of the twenty-fifth anniversary of the establishment of submarine cable communication with the Far East is to be celebrated at the Imperial Institute this evening. The Prince of Wales and the Duke of Cambridge will be present. A distinctive feature of the proceedings will be the arrangements made for entering into direct communication with different parts of Europe, Asia, and Australasia, Africa, and America. The apparatus for effecting this will be grouped on the four corners of a large table placed in the centre of a room, and from the different instruments messages will be despatched and answers received while the Prince of Wales remains in the room. Among other communications, the Prince of Wales will send a message to the Viceroy of India. It is anticipated that Lord Elgin's reply from India will be handed to his Royal Highness within 150 seconds of the despatch of the message from the room.

Large Electric Motor.—At a recent meeting of the Société Internationale des Electriciens, M. J. Rey presented a communication on the efficiency of a 720-h.p. motor. This motor, which has been constructed by MM. Sautter, Harlé, and Co., is intended for driving the submarine boat, the "Gustave Zédé." It is of the six-pole type, and has two equal armatures coupled in quantity and arranged on a common shaft. The measurement of the commercial efficiency of this motor has been carried out according to the Hopkinson method, suitably modified, and which consists in connecting rigidly the two armatures opposed to each other, one working as a motor and the other as a generator. M. Rey gave details of the tests and the calculations made therefrom, and from which it appeared that the commercial efficiency was equal to 92·44 per cent. The efficiency calculated before the motor was constructed was 92·15 per cent. The author concluded by stating that it is possible to construct powerful direct-current motors which will only vary by 1 per cent.

Digitized by Google

from the estimated efficiency and that obtained when the machines are built.

Electricity at the Antwerp Exhibition.—Before the Société Internationale des Electriciens on the 4th inst., M. L. Brunswick presented a communication on a visit to the Antwerp Exhibition. He stated that the exhibition only comprises direct-current machines which have interesting constructive features, among others mentioned being the Manchester type of the Compagnie Internationale d'Electricité de Liège. Only one German firm, that of Schuckert and Co., makes a display, the company being the suppliers of search-lights to the Belgian Government. The lighting of the exhibition is effected by 220 arc lamps and 1,500 incandescents, the work having been carried out by MM. Dulait and Pieper. The electric motors in operation during the day drive ventilators, pumps, and mining plant. The navigable balloon is not yet at work. Among the steam-engines mentioned by M. Brunswick as being shown are those of the Corliss, Sulzer, Willans, and Brown types.

Cost of Working an Electric Elevator.—Mr. Morgan I. M. Williams, A.M.I.C.E., gives the following statement as to the cost of working an electric elevator. The elevator in question was erected under his supervision for Mr. E. D. Stern, at 4, Carlton House-terrace, at the commencement of the present year; the contractors for the work being the Otis Elevator Company. The elevator itself is fitted with a 600lb. car, having a rise of 40ft., and designed to work at the rate of 60ft. per minute, and is fitted with all the latest improvements in regard to self-acting safety appliances. It is operated from within by a simple regulating switch, which can be worked quite well by a woman or child; and everything has so far given great satisfaction. The current is supplied from the mains of the local supply company, whose invoice for the last quarter shows that the cost of current for working during the last three months amounts to the sum of 9s. 2d., during which time the lift has been in regular use, the number of trips being probably about 400, the cost of an average journey amounting to from one farthing to one-third of a penny, according to the load.

Indicating the Position of Vessels.—Before the Royal United Service Institution recently, Lieutenant Charles W. Sleeman, R.N., described an invention claimed to be applicable to any vessel designed to be run and directed without human agency actually present in the vessel itself—*i.e.*, by means of an electric cable "paid out" from the vessel as she proceeded ahead. Its purpose was to indicate the point of the compass on which such a vessel was heading at any moment during its run, this being notified to the person at the distant station who is directing the vessel or torpedo. The invention, which Lieutenant Sleeman explained by means of models and drawings, consists of an ordinary ship compass electrically combined with a specially devised reversible "step-by-step" instrument, and a small battery. These are placed in the vessel, and a recording key instrument, a galvanometer, and another small battery are required at the station from which the vessel is directed. When the vessel or torpedo is in the water ready for running, and with all the wires connected, the operator, the lecturer stated, can ascertain in what direction the vessel is pointing by moving his key until the galvanometer is deflected. Subsequently the operator has only to watch the galvanometer, and by moving his key he is enabled to regulate the course at will to any point of the compass. The steering of the vessel, or torpedo, as the lecturer explained, was a function of control altogether apart from and independent of his "compass-steering invention." He claimed that by his invention "a controllable vessel" of any kind could be steered on a compass course, even when entirely invisible to the operator, and quite as readily as though the operator were actually on board, instead of at a considerable distance. The "compass-steering" invention was originally worked out with the object of applying it to controllable torpedoes, in order to avoid the use of the masts or floats attached to these weapons in such manner as to be visible to the operator.

Tic Douloureux and Electricity.—In reference to the note on this subject in our last issue, Mr. W. S. Hedley, M.D., writes to the *Lancet* as follows: "The letter of Dr. Althaus lends support to the contention that in cases of trigeminal neuralgia surgical interference ought, as a rule, to be withheld until electrical treatment has been duly tried. The long-continued application of very weak continuous currents, as advocated by Dr. Althaus, is a proceeding of recognised value, and had the more rapid expedient failed, it would doubtless have been proper in the case quoted to persevere in the use of other and slower methods. By a sublime effort of faith and patience the application of the fractional part of a milliampere of continuous current for an hour a day during a period of three successive weeks might even have been carried out. It is, however, to avoid such a necessity that I venture to suggest a trial of this quicker procedure when the current in question is available, and the medical man knows how to handle it. In gauging the relative merits of various methods, it is not to be forgotten that a course of treatment extending over a period of three weeks allows to come into play so many other possible factors in the process of cure that it becomes proportionately difficult to distinguish the exact relationship of cause and effect. This can scarcely be mistaken in the case referred to. It is cited as an instance in which the results of a single electrisation are certainly not less striking, and possibly not less permanent, than those claimed for one of the most difficult operations known to surgery."

Detecting the Presence of Electric Oscillations. Prof. Elihu Thomson, in the New York *Electrical Engineer* of July 4, mentions the following curious and rather amusing illustration of the principle upon which the beautiful instrument for detecting the presence of electric oscillations devised by Dr. Lodge, and called by him the "coherer," is based: "It was reported to me when in Philadelphia that a certain electroplater had found that he could not pursue his silver-plating operations during thunderstorms, and that if he left his plating over night and a thunderstorm came up the work was invariably ruined. I was disposed to be thoroughly sceptical, and expressed my disbelief in any such effect. Being urged, however, I went to the silver-plater's shop, which was a small one, and questioned the silver plater himself concerning the circumstance which had been reported. While it was evident that he was not a man who had informed himself electrically, I could not doubt that, after conversing with him, he had indeed been stating what was perfectly true—namely, that when his operations of plating were going on and a thunderstorm arose, his batteries, which were Smee cells, acted as though they were short-circuited, and the deposit of metal was made at too rapid a rate. The secret came out on an inspection of his connections. The connections of his batteries to his baths were made through a number of bad contacts, which could not fail to be of high resistance under ordinary conditions. I could readily see that virtually he was working through a considerable resistance and that he had an excess of battery power for the work. Under these circumstances a flash of lightning would cause coherence of his badly contacting surfaces, and would improve the conductivity so as to cause an excessive flow of current,

Digitized by Google

give a too rapid deposit, and—as he put it—'make the batteries boil.' The incident suggests the use of Dr. Lodge's ingenious instrument in the study of the waves which are propagated during thunderstorms, of which waves we have practically little or no information."

Village-Lighting.—An excellent example of village illumination is to be found at Auffay, which has a population of 1,500 persons distributed over an area of about a square mile. About 800 metres from the centre of the town there was a fall of water actuating an ancient type of waterwheel capable of giving a maximum of 7 h.p. This wheel has been replaced by a Hercules turbine of 12 h.p., running at 145 revolutions a minute, whilst a steam-engine of equal power has been put down as reserve. Having thus provided a regular power, the company established in adjoining buildings wood-working machines, and leased them to a carpenter on condition that he superintended the working of the dynamo serving to light the village. The distribution is effected at 110 volts notwithstanding the rather considerable extent of the service; a feeder is carried 800 metres, and the most distant lamp from the end of the feeder is about 800 metres. The loss provided for in the feeder is 15 volts, and the loss from the arrival point of the feeder to the lamps is from two to three volts. The weight of copper in the mains, which are arranged for 250 lamps, is about six tons, and of the 250 lamps 120 are already connected to the network. The generating station contains a single dynamo of the Postel-Vinay type, giving 80 amperes at 120 volts, and space is available for a second machine. The pressure at the end of the feeder is kept constant by an automatic rheostat, and as the dynamo runs without displacement of the brushes and without sparking, it is only necessary to start the dynamo at dusk and leave it to work at its own sweet will. The turbine and steam-engine generally work simultaneously during the daytime, but at night, when the carpenter has finished work, the steam-engine is stopped and the turbine alone remains in operation. The public illumination is effected by means of 32 16-c.p. lamps and one of 32 c.p. It is stated that notwithstanding the small number of lamps in use (120) the working results during 1893-94 allowed of a distribution of a remunerative dividend on the total capital expenditure.

The Proposed Pacific Cable.—A "Civil and Electrical Engineer," writing in the *Sydney Daily Telegraph* (New South Wales) with reference to the Eastern Extension Telegraph Company's offer to construct and lay down the projected Pacific cable for the British Government if supported by English money, says that this information is not surprising to persons who have seen the obstacles placed in the way of this great undertaking by the above-named "octopus" company. Canada, he states, has from the first taken the lead in this business, leaving Australia to play seconds. What the English Government will do is unknown, but he does not think they will interefere with cable construction, as they have always very properly left that to private enterprise. He is of opinion that this Pacific line of communication would have been completed long ago but for the hostility of Sir John Pender and Co. They put forth various reports in the Press to the effect that the proposed speaking distances on the new line would be too great for any electric signals to be understood; also that the ever active volcanic eruptions would soon destroy any cable if laid down in that part of our spheroid. This the writer, a practical electrical engineer, denies *in toto*. He points out that this company have the whole of the Australian lines of cable communication in their hands already, which accounts for their most liberal and strategic offer to the home Government, knowing, as they do, that the colonies have had quite enough of their monopoly, and that their grasping proposal would not for a moment be entertained in Australia. Of course, there are other extensive works in London which are quite as capable of carrying out the scheme as Sir John Pender and Co. But why not, he asks, erect works and manufacture the cable out here, submerge and work by an electrical staff appointed by the colonies? A cable factory is very much wanted in Australia for the manufacture of electric lighting, telegraph, and insulated wire, wire cables for tramways, etc., and the writer would be pleased to see a new company formed to carry out these ideas.

Important Agreement between German Firms. The agreement which has for some years existed between the Allgemeine Elektricitäts Gesellschaft (General Electricity Company of Berlin) and Messrs. Siemens and Halske has now been terminated. By the determination of this understanding the limitations imposed upon the former in the direction of constructing machinery and in carrying out installations have been removed. With a view to give effect to this important change, the Allgemeine Company propose to considerably enlarge their works and to lay themselves out for the building of the largest types of machines for central-station work. Special attention is to be paid to the electrical transmission of power, and in this connection it is interesting to note that the rotary-current system worked out by the company, and which formed the basis of the Lauffen transmission plant, will be largely applied. The extent of the company's works will be readily understood when it is mentioned that no less than 3,500 workpeople are engaged in them. Simultaneously with the termination of the above-mentioned agreement, a new arrangement was arrived at, which is continue for 10 years commencing with 1887. The details of the new agreement show that the construction and working of central stations, both in Germany and abroad, will be carried out by the two companies co-operatively, that the restriction of each dealing with isolated installations will be removed, and the considerable sacrifices made by both firms having established works for the construction of incandescent lamps, and which led to ruinous competition in prices between them, will be brought to an end by a mutual convention. Coupled with this agreement is a condition that the undertaking shall be independent of foreign Edison companies, and for this purpose Messrs. Siemens and Halske have purchased the rights of the Paris Compagnie Continentale Edison for £40,450, of which £13,500 is taken up by that firm, and £17,500 by those firms taking up new shares in the Allgemeine Company. A fresh arrangement has, moreover, been arrived at concerning the supply of cables.

Electrical Affairs in Spain.—A Madrid correspondent of *L'Electricien* states that it is very difficult to obtain information in Spain so as to prepare statistics concerning the electricity works in operation. Everybody refuses, he says, either to give details, or furnishes incorrect information so as to prevent the actual conditions of the works from reaching the ears of the members of the financial administration. Thus a station in which there are two 50-h.p. machines will state that it has two of 20 h.p., because the taxes amounts to 20 pesetas per horse-power per annum. Moreover, as the taxes on manufactures are very high, everybody endeavours to carefully conceal figures which could be utilised by the fiscal agents. The correspondent says that the General Gas Company of Madrid has just purchased at 100 per cent. premium the whole of the shares of the Madrid Electricity Company which were held by the General Electricity Company of

Digitized by Google

Berlin. There are in Madrid two large companies and three small central stations, whilst another is about to be constructed. The two important companies are the Compañia Madrilena de Electricidad, which supplies 70,000 lamps to 3,000 subscribers, and the Electricity Supply Company for Spain, which furnishes about the same number of lamps. Of the small stations mentioned, one which was originally built for the lighting of the Princesa Theatre has a capacity of 6,000 lamps; the second, for the illumination of the Lara Theatre, supplies 1,500 lamps in the neighbourhood; the third station has an output of 200 amperes. About 600 lamps are energised from a station situated at Carabanchel, a small village 3¾ miles out of Madrid, and the owners have asked for permission to erect a large station in the Barrio Salamanca in Madrid. All the companies, the correspondent continues, are doing a good business and making money, but the one which has prospered the most is the Compañia Madrilena, which has just paid a dividend of 11 per cent. By the purchase of the shares hitherto held by the General Electricity Company of Berlin, as mentioned above, the undertaking has passed entirely into the possession of the Madrid Gas Company.

The Caen Electricity Works.—The central electric light station of the Société Régionale d'Electricité (Normandy district) at Caen was set in operation on the 9th ult. The system adopted is the alternating-current method at 2,400 volts; the cables are laid underground, and transformers placed at suitable intervals reduce the current from 2,400 to 110 volts. The current thus transformed, according to an article in *L'Electricien* of the 14th inst., is then distributed to consumers by means of an overhead three-wire system, which is supplied by feeders connected to the groups of transformers arranged with two secondary circuits in series. The difference of potential between the two outer conductors is 220 volts. Concentric cables of the Fowler type are used; they are placed in wooden conduits covered with tar at a depth of about 20in. below the ground level. In order to eliminate weak points from the mains no splicing has been carried out, the cables being in one piece between each group of transformers. The low-pressure distributing system consists of bare copper conductors of high conductivity supplied by the Maison Geoffroy-Delore, and carried on porcelain insulators arranged on struts. At each crossing the neutral wires are connected together, as are also the wires of each bridge. The generating station has been erected on the Promenade du Fort on the banks of the Grand-Odon, the water from which is used for feeding the boilers and for condensing purposes. Provision has been made in the engine-room for three groups of Willans-Ferranti combinations, but only one set is now at work. It comprises a Willans compound engine, running normally at 380 revolutions a minute, and coupled direct to a Ferranti alternator of a capacity of 55 amperes at 2,400 volts; the exciter, which is arranged on the alternator shaft, gives 60 amperes at 110 volts. A second group has been ordered, and will soon be laid down. Steam is supplied by two Babcock and Wilcox boilers, and a third is shortly to be erected. There are six banks of transformers in the town; they are of the Labour type, are all connected in shunt to the high-pressure circuit, and their secondaries are placed two in series. They are arranged for 80 periods, and to convert the current from 2,400 to 110 volts. Being connected two in series on the secondary, a neutral point is produced at the junction of the circuits of the two transformers, and a difference of potential of 220 volts between the extreme terminals. The station has already 4,000 lamps connected to the mains. It has been carried out according to the designs of Mr. Ferranti and M. Leroy, the latter of whom is engineer-in-chief to the Compagnie Nationale d'Electricité. M. Lecornu, who was for some time at the Troyes station, has been appointed engineer-in-charge.

Awards Offered for Electrical Papers. — The Société Industrielle de Mulhouse has recently issued the programme of prizes to be awarded in 1895 for papers and designs which are to be addressed to the president of the Société by February 15, 1895. Among the prizes offered the following may be cited: A silver medal for any application of electricity in the printing industry; and a similar medal for a registering pyrometer which will determine the temperature of gaseous products of combustion of coal in steam-boilers. The apparatus desired is one capable of indicating with an approximation of at least 5 per cent. the temperature of a gaseous current in the flue of a steam-boiler between the limits of 300deg. and 800deg. As the apparatus will be plunged into the gas, the indicator of the temperature must be placed outside the mass of the furnace in order to render readings easy of being taken. The prize will only be awarded to an apparatus which has for at least some months been applied to a steam-boiler working in Upper Alsace. A medal of honour is offered for a practical installation carried out in an industrial establishment in Upper Alsace, with a view to the distribution of motive power to various machines or apparatus by means of electricity obtained from either a public or private generating station. The installation must have been in practical operation for a year, and must have the advantages of showing an appreciable economy over the method of distribution hitherto employed. A medal of honour will be awarded for an electric motor capable of developing power and a variable speed at will. The power of the motor is to be 10 h.p. or less. Either a silver or bronze medal of honour or a sum of money is offered for a simple and practical method of connecting armature coils to the commutator segments of dynamos. This new system must allow of one easily changing, and in a relatively short space of time, the commutators of dynamos. It must ensure a good contact of the coils with the commutator segments and must not cause damage to the wires, as happens with binding screws. Commutators with air insulation between the segments are out of the question. The paper describing this method must enumerate the advantages and the inconveniences of the systems already in use, and compare them with the new method. A comparison between electric and gas illumination is desired, and for this a medal of honour is to be presented. The paper is to deal with the comparative expenditure of an electrical installation and of a gasworks having to serve in each case a population of 30,000. The comparison is to specially treat the following points: (1) costs of installation of the central station and of the gasworks, of the electrical distribution, and mains from the generators to the houses; (2) cost of coal required for producing power in the generating station and gas in the gasworks; and (3) the working expenses and maintenance in each case. A special chapter is to be devoted to a detailed estimate of the expenses and receipts resulting in the case of the gasworks of the value of the by-products of distillation. Another chapter is to treat of the photometric value of gas jets for a given consumption, and of the number of electric lamps which would be substituted for them. It will be convenient, in fact, in the comparison to keep account of the fact that the substitution of the electric light for that of gas permits generally of an increase in the illuminating power.

REACTANCE.*

BY CHARLES PROTEUS STEINMETZ AND FREDERICK BEDELL.

The term "reactance," which has been used and advocated by the writers and others, and which has been officially adopted at our suggestion by the American Institute of Electrical Engineers at its Philadelphia meeting, is one which assumes particular importance now that the term "inductance" is defined as synonymous with the "coefficient of self-induction," usually symbolised by the letter "L." Reactance is a quantity similar in many respects to resistance, but the E.M.F. in overcoming reactance consumes no power, for it is at right angles to the current.

The impressed E.M.F. in an alternating-current circuit may be divided into two components: first, the power E.M.F. in the direction of the current; and second, the reactive E.M.F. in quadrature with the current to overcome the reactance. The reactive E.M.F. is the product of the current and the reactance. The reactance is accordingly equal to the component of the impressed E.M.F. at right angles to the current divided by the current. Reactance is measured in ohms.

The reactive E.M.F. in the circuit may be due to self or mutual induction, to capacity or to some outside counter E.M.F. produced by a motor or other device. In general, in any alternating-current circuit,

$$\text{Impressed E.M.F.} = \sqrt{\text{Power E.M.F.}^2 + \text{Reactive E.M.F.}^2};$$

that is, the impressed E.M.F. is the vector sum of the E.M.F. which transmits power and the reactive E.M.F.

Reactance tends to cause a phase difference between current and E.M.F. If θ represents this angle of phase, we have the relation,

$$\tan\theta = -\frac{\text{reactance}}{\text{resistance}}.$$

When θ is negative, the current lags behind the E.M.F.; when θ is positive, the current is in advance of the E.M.F. The expression for the instantaneous value of the current may be written

$$i = I \sin(\omega t + \theta),$$

or

$$i = \frac{\text{Impressed E.M.F.}}{\text{Impedance}} \sin\left\{\omega t - \text{arc tan}\frac{\text{reactance}}{\text{resistance}}\right\}.$$

A few illustrations of particular cases will make the use of the term reactance more clear.

Circuits Containing Resistance and Inductance.—In a simple circuit containing resistance and inductance, the reactance is equal to $L\omega$—that is, it is 2π times the product of the inductance and frequency. The impedance being the vector sum of the resistance and reactance, is

$$\text{Impedance} = \sqrt{R^2 + L^2\omega^2},$$

where $\omega = 2\pi \times$ frequency. In this case all the power is used in overcoming resistance, and the power E.M.F. is equal to the ohmic E.M.F. RI. The reactive E.M.F. is equal to the inductive E.M.F., $L\omega I$; hence

$$\text{Impressed E.M.F} = \sqrt{\text{Power E.M.F.}^2 + \text{Reactive E.M.F.}^2},$$

or

$$\text{Impressed E.M.F.} = \sqrt{\text{Ohmic E.M.F.}^2 + \text{Inductive E.M.F.}^2}.$$

The impressed E.M.F. in this case is the vector sum of the E.M.F.'s necessary to overcome resistance and inductance.

A consideration of Figs. 1 and 2 (in which positive direction is counter clockwise) will show that the reactance and reactive E.M.F. are positive in the case of a circuit containing inductance. The impressed E.M.F., which is the sum of the two, is therefore in advance of the current, which is in the same direction as the power or ohmic E.M.F. The current is indicated by a closed arrow in the figures. The same, however, may be otherwise expressed if we take the impressed E.M.F. as our direction of reference, by saying that the current lags behind the E.M.F. by the angle θ, which angle is negative, therefore, for circuits with inductance according to the relation

$$\tan\theta = -\frac{\text{reactance}}{\text{resistance}} = -\frac{L\omega}{R}.$$

* A paper presented at the Philadelphia meeting of the American Institute of Electrical Engineers.

The value of the current at any instant is given by the equation

$$i = \frac{E}{\sqrt{R^2 + L^2\omega^2}} \sin\left(\omega t - \text{arc tan}\frac{L\omega}{R}\right).$$

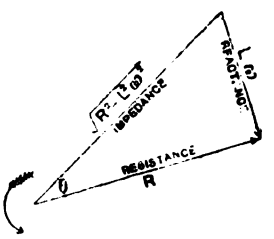

FIG. 1.

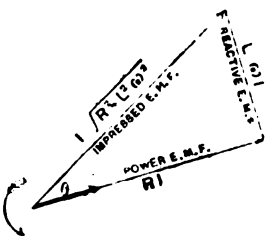

FIG. 2.

Circuits Containing Resistance and Capacity.—In such circuits the reactance is equal to $-\frac{1}{C\omega}$, where C, capacity, and $\omega = 2n \times$ frequency—that is, it is negative. The reactive E.M.F. is also negative, being equal to $-\frac{I}{C\omega}$. This negative reactance gives a positive value to the angle θ, and the current is accordingly in advance of the E.M.F. We have then

$$\text{Impedance} = \sqrt{R^2 + \frac{1}{C^2\omega^2}},$$

and

$$\tan\theta = -\frac{\text{reactance}}{\text{resistance}} = +\frac{1}{CR\omega},$$

similar to the corresponding equations above. The instantaneous value of the current is given by the equation

$$i = \frac{E}{\sqrt{R^2 + \frac{1}{C^2\omega^2}}} \sin\left(\omega t + \text{arc tan}\frac{1}{CR\omega}\right).$$

These relations are shown in Figs. 3 and 4.

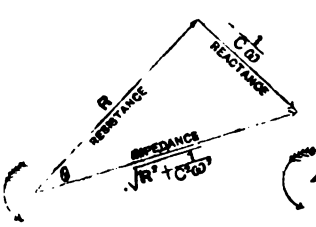

FIG. 3.

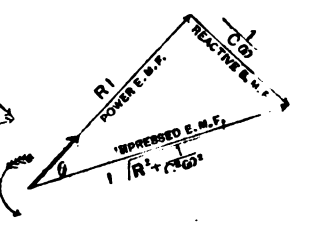

FIG. 4.

Circuits Containing Resistance, Inductance, and Capacity.—In a circuit containing inductance and capacity the reactive E.M.F. is the sum of the inductive E.M.F. and the condenser E.M.F.—that is, $L\omega I - \frac{I}{C\omega}$. The reactance is similarly the sum of two terms, $L\omega - \frac{1}{C\omega}$; thus, the reactance is positive or negative according to whether the inductive E.M.F. is greater or less than the condenser E.M.F. Whether the current is behind or ahead of the impressed E.M.F. depends upon the same condition, for

$$\tan\theta = -\frac{\text{reactance}}{\text{resistance}} = \frac{1}{CR\omega} - \frac{L\omega}{R}.$$

The value of the current at any instant is

$$i = \frac{E}{\sqrt{R^2 + \left(L\omega - \frac{1}{C\omega}\right)^2}} \sin \left\{\omega t + \text{arc tan}\left(\frac{1}{CR\omega} - \frac{L\omega}{R}\right)\right\}$$

The diagrams in Figs. 5 and 6 illustrate the case of a single circuit containing resistance, inductance, and capacity. In the case here represented, the condenser E.M.F. is

Digitized by Google

greater than the inductive E.M.F., and the current is therefore in advance.

Circuits Containing Mutual Induction. — To further exemplify the use of the term reactance, let us consider a circuit containing a transformer. Besides the E.M.F.'s already discussed, we must consider the back E.M.F. due to the influence of the secondary upon the primary circuit. This may be resolved into two components—one in the same direction as the current, and the other in quadrature with it, which will form part of the power E.M.F. and reactive E.M.F. respectively. The E.M.F. introduced by a motor is treated in the same way.

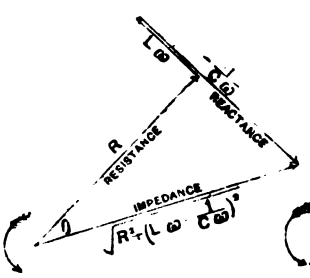

FIG. 5.

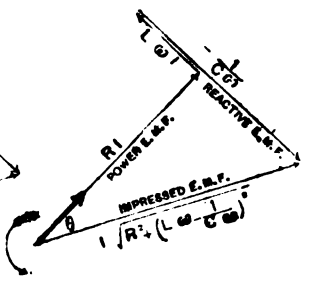

FIG. 6.

These illustrations will suffice to show the method by which any E.M.F. in a circuit is resolved into two components—one in the direction of the current, which therefore transmits power, and the other at right angles to the current, which represents no power, but simply overcomes the reactance.

It is to be borne in mind that the terms here given may be used in all alternating-current circuits, whether the current is harmonic or not; for when the current is not strictly harmonic we may consider it equivalent to an harmonic current. The equivalent harmonic current and equivalent harmonic E.M.F. have the same square root of mean square values as the actual current and E.M.F., and have such relative phase positions that the same power is transmitted.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

VI.

BY ALFRED E. WIENER.

14. *Weight of Armature Winding.*—A copper wire of one circular mil $\left(= \frac{1}{1{,}000{,}000} \times \frac{\pi}{4} \text{ square inch}\right)$ area weighs ·00000303lb. per foot of length; our armature conductor of δ^2_a circular mils sectional area, therefore, has a weight per foot of ·00000303 × δ^2_a pound. And the total L_t feet of it used in winding the armature will weigh:

$$\text{lb.}_a = \cdot00000303 \times \delta^2_a \times L_t \quad . \quad . \quad . \quad . \quad (28)$$

lb._a = weight of bare armature winding, in pounds;
δ^2_a = sectional area of armature conductor in circular mils, from formula (4);
L_t = total length of armature conductor, in feet, formulæ (19) to (27) respectively.

In case of round gauge wires, the product ·00000303 × δ^2_a is contained in the gauge table under the heading "lbs. per foot," and consequently the bare weight of the winding is found by simply multiplying the respective table value by the total length, L_t, and eventually by the number of wires, p, stranded in parallel.

If, in case of heavy rectangular or wedge-shaped armature bars, the cross-section, δ^2_a, is given in square inches, the numerical constant in the above formula (28) should be replaced by 3·858, this being the weight per foot of a copper bar of one square inch sectional area.

When standard gauge wire is to be employed in winding the armature, it is desirable to know the weight of the winding, including its covering, particularly in the case when insulated wire, such as is obtainable from wire manufacturers, is to be used. This covered weight of the winding can be expressed as a multiple of the bare weight by the equation:

$$\text{lb.}_a = k_5 \times \text{lb.}_a = \cdot00000303 \times k_5 \times \delta^2_a \times L_t \quad (29)$$

in which k_5 is a constant depending upon the ratio of the bare diameter of the wire to the thickness of its insulation. In the following Table XXI. these ratios and the corresponding values of k_5 are given for all standard gauge wires likely to be used for winding armatures, for single and for double cotton covering:

TABLE XXI.—Weight of Insulation on Round Copper Wire.

Gauge of wire. B.W.G.	Gauge of wire. B. & S.	Diameter of wire (bare inches).	Single cotton insulation. Thickness of insulation, inches.	Ratio of bare diameter to thickness of insulation	Weight of insulation in per cent. of covered wire.	Weight of covered wire in per pound of bare k_5.	Double cotton insulation. Thickness of insulation, inches.	Ratio of bare diameter to thickness of insulation.	Weight of insulation in per cent. of covered wire.	Weight of covered wire in per pound of bare k_5.

* Double silk: 1 mil of silk insulation taken equal in weight to 1·25 mil of cotton covering.

15. *Armature Resistance.*—The electrical resistance of the armature winding can be determined by the total length of wire wound on the armature, and from the sectional area of the conductor. If R denotes the total resistance of the armature wire, all in one continuous length, and if the machine has P pairs of magnet poles, and therefore 2 P electrically parallel armature portions, then the armature forms the combination of 2 P parallel branches of $\frac{R}{2P}$ ohms resistance each (see Fig. 13). The joint resistance of these 2 P circuits—that is, the actual armature resistance—will consequently be

$$r_a = \frac{R}{(2P)^2} = \frac{R}{4 \times P^2},$$

* From the *Electrical World* (New York).

Digitized by Google

The total resistance, R, of all the armature wire in series can be calculated from the total length, L_t, and the sectional area, δ^2_a, of the conductor by the formula

$$R = L_t \times \frac{10{\cdot}5}{\delta^2_a},$$

where 10·5 is the resistance, in ohms, at 15·5deg. C. (=60deg. Fahr.), of a copper wire of one circular mil sectional area and 1ft. length, and of a conductivity of about 98 per cent. of that of pure copper. The quotient $\frac{10{\cdot}5}{\delta^2_a}$, for commercial copper, or $\frac{10{\cdot}32}{\delta^2_a}$ for chemically pure copper, represents the resistance per foot of the armature conductor, and can, for every standard size of wire, be taken from the wire gauge table.

Introducing the value of R into the above equation, we obtain the following formula for the resistance at 15·5deg. C. of any armature having a single conductor:

$$r_a = \frac{1}{4 \times P^2} \times L_t \times \left(\frac{10{\cdot}5}{\delta^2_{a_1}}\right) \quad . \quad . \quad (30)$$

r_a = resistance of armature winding at 15·5deg. C., in ohms;
P = number of pairs of magnet poles, eventually half the number of parallel armature portions;
L_t = total length of armature conductor, in feet, formulæ (19) to (27) respectively;
$\delta^2_{a_1}$ = sectional area of armature conductor, in circular mils, formula (4).

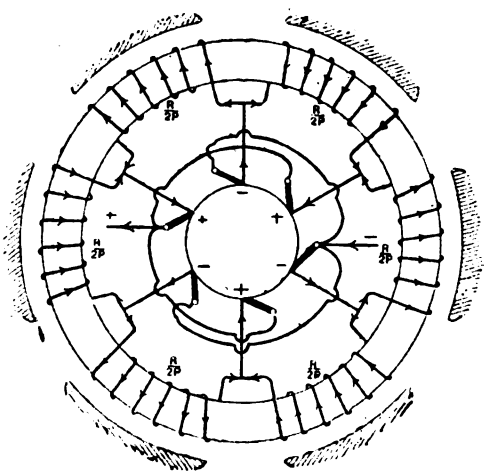

Fig. 13.

In an armature each conductor of which consists of p parallel strands of wire of $\delta^2_{a_1}$ circular mils sectional area, there are 2 P parallel circuits of p wires each, or altogether $2 \times P \times p$ parallel circuits of $\frac{R}{2 \times P \times p}$ ohms resistance each; the joint resistance therefore is

$$r_a = \frac{R}{4 \times P^2 \times p^2},$$

and since in this case the total resistance of the whole armature wire in series is

$$R = L_t \times p \times \left(\frac{10{\cdot}5}{\delta^2_{a_1}}\right),$$

we obtain for the resistance at 15·5deg. C. of any armature winding consisting of p strands of wire of $\delta^2_{a_1}$ circular mils sectional area, the formula

$$a = \frac{1}{4 \times P^2 \times p^2} \times L_t \times p \times \left(\frac{10{\cdot}5}{\delta^2_{a_1}}\right)$$

$$= \frac{1}{4 \times p \times P^2} \times L_t \times \left(\frac{10{\cdot}5}{\delta^2_{a_1}}\right) \quad . \quad (31)$$

In formulæ (30) and (31) the number of pairs of poles, P, is to be replaced by half the number of parallel armature portions if these two numbers differ from each other.

In order to obtain the armature resistance at any other temperature higher than 15·5deg. C., add 1 per cent. for every 3deg. C. over 15·5deg. C. The resistance, r_a, at 15·5deg. C. being known, the armature resistance at t deg. C. consequently will be

$$(r_a)_{t\,\text{deg.}} = r_a + \frac{1}{100} \times r_a \left(\frac{t\,\text{deg.} - 15{\cdot}5\text{deg.}}{3}\right)$$

$$= r_a \times \left(1 + \frac{t\,\text{deg} - 15{\cdot}5\text{deg.}}{300}\right) \quad . \quad (32)$$

16. *Energy Losses in Armature.*—There are three sources of energy dissipation in the armature which are transformed into heat: (1) overcoming of electrical resistance of armature winding; (2) overcoming of magnetic resistance of iron; and (3) generation of electric currents in the armature core.

a. Energy Dissipated in Armature Winding.—The energy required to pass an electric current through any resistance is given, in watts, by the product of the square of the current intensity, in amperes, into the resistance, in ohms. The energy absorbed by the armature winding, therefore, is:

$$w_a = C^2 \times r'_a \quad . \quad . \quad . \quad . \quad . \quad (33)$$

where w_a = energy dissipated in armature winding, in watts;
C = total current generated in armature in amperes;
r'_a = resistance of armature winding, hot, in ohms; see formulæ (30), (31), and (32).

The total current, C, in series-wound dynamos is identical with the current output, c; in shunt and compound wound dynamos, however, C consists of the sum of the external current, c, and the current necessary to excite the shunt magnet winding. The amount of current passing through the shunt winding is the quotient of the potential difference, e, at the terminals of the machine, by the resistances of the shunt circuit, r_m—that is, the sum of the resistance of the shunt winding and of the regulating rheostat, in series with the shunt winding.

For the resistance, r_a, of the armature winding, when hot—in order to be on the safe side in determining the armature losses—that at about 75deg. C. should be taken, or, according to formula (32), the resistance, r_a, at 15·5deg. C. multiplied by $\left(+1\frac{75\text{deg.} - 15{\cdot}5\text{deg.}}{300}\right) = 1{\cdot}2$.

The energy dissipated in overcoming the resistance of the armature winding consequently can be obtained from the formula:

$$w_a = 1{\cdot}2 \times \left(c + \frac{e}{r_m}\right)^2 \times r_a \quad . \quad . \quad . \quad (34)$$

If w_a is to be computed before the field calculations are made—that is to say, before r_m is known—it is sufficiently accurate for practical purposes to express from experience the total armature current, C, as a multiple of the current output, c, and, therefore, we have approximately

$$w_a = 1{\cdot}2 \times (k_6 \times c)^2 \times ra \quad . \quad . \quad . \quad . \quad (35)$$

and in this the coefficient k_6 can be taken from the following table:

Table XXII.—Total Armature Current in Shunt and Compound Wound Dynamos.

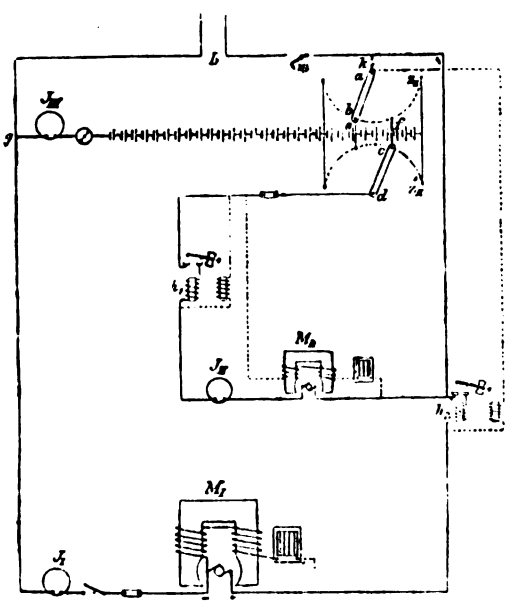
THE ZURICH-HIRSLANDEN ELECTRIC TRAMWAY.

A NOVEL DEPARTURE.

A novel departure in electric tramway working has been made in the case of the Zürich-Hirslanden tramway, which was set in operation on March 8 last. This deviation from the practice hitherto followed consists in the employment of accumulators installed in the power station in conjunction with the generating dynamos, so as to meet the varying conditions of the load on the line. The Oerlikon Engineering Works, at the suggestion of the Hagen Accumulator Works, decided to introduce this system for general traction work, they having experienced good results with an experimental line laid down at the Oerlikon factory.

As will be seen from the diagram of connections, which, together with the accompanying description, is abstracted from the *Elektrotechnische Zeitschrift*, the principal shunt dynamo, M_1, is directly connected with the line, L, with which the battery of accumulators is united in parallel. If a large quantity of current is being consumed on the line, the battery assists the dynamo in supplying current; but when the demand for current is small, the accumulators are charged so that the dynamo delivers a constant current, and the steam-engine is equally loaded continuously, and works most economically. The discharging switch, *a b*, of



the double-cell regulator, z_1 z_2, is arranged automatically, and is therefore always automatically set to the requisite pressure. The dynamo, M_1, charges, as will be observed, only the cells between *e* and *g*. In order, however, to be able to charge the cells between both cell switches, *a b* and *c d*, and also between *e* and *f*, a smaller shunt dynamo, M_{11}, is inserted between the two switches mentioned. The magnet coils of the dynamo also lie between both these points, so that if the lever, *a b*, changes its position on account of its automaticity, the magnetic field, influenced by the cells more or less connected, is likewise more or less excited, so that the charging current strength of the regulator cells remains as much as possible constant. In the conductor of this machine is inserted an automator switch, h_1, which, as soon as the pressure of the regulating cells for any reason becomes higher than that of the dynamo, automatically disconnects the conductor of the machine, and also re establishes the connection when the pressure of the dynamo becomes greater than that of the regulating cells. A similar automatic switch is placed in the conductor of the main dynamo. The battery is provided with a lead safety fuse, and the trolley line with an automatic cut-out switch, which disconnects the line on a short-circuit taking place. The current strength of the dynamos, M_1 and M_{11}, and of the battery may be ascertained at any time by the ammeters, J_1, J_{11}, and J_{111}.

The length of the tramway is 2½ miles, and the gradients are heavy. Each car will accommodate 24 passengers. The generating station is at Hirslanden. It contains two Galloway boilers, provided by Messrs. Escher, Wyss, and Co., of Zurich, two 90-h.p. steam-engines and one of 5 h.p., two shunt dynamos, giving each 100 amperes at from 450 to 550 volts, and a shunt dynamo yielding 30 amperes at 100 volts. The battery, which was supplied by the Hagen Accumulator Company, comprises 300 cells, having a capacity of 245 ampere-hours. Practical experience shows that the use of accumulators in this direction is of considerable advantage.

NOTES ON ELECTRIC TRAMWAYS IN THE UNITED STATES AND CANADA.*

BY H. D. WILKINSON, MEMBER.

During the period of the Chicago Exposition last year I had opportunities of looking into systems of street traction in that city, and of discussing points of immediate interest with engineers from different cities whom it was my privilege to meet.

For several weeks previous to the opening of the exposition the scene for miles round was one of the greatest activity in the construction of street tramways, centring from all districts on the south side, and forming connections from the city main cable car lines. The continuation of the elevated steam road to the exposition along Sixty-fourth-street was also a smart piece of work, including the erection of six stations and a pin-connected truss bridge across the Illinois Central Railroad track without obstructing traffic. Immediately this line was finished trolley wires were strung underneath the girders, and the previous horse car lines, which had grown totally inadequate to the traffic, were converted into electric lines. The motor cars were rarely without trailers, and in the busiest times of the day two, and sometimes three, fully-loaded passenger cars were hauled. The term "fully loaded," when applied to cars in America, must be understood in its most literal sense. Besides all standing and sitting room being taken up inside, the drivers' and conductors' platforms are closely packed, and people cling to the outsides wherever there is the smallest foothold. More than this, I have seen cars on busy days with people sitting on the window-ledges and climbing on the roof, and the back end of the car framework weighted out of shape and scraping the ground. After seeing one motor car hauling two or three trailers, with 250 people, at the rate of 10 miles an hour, on roads with no drainage, and covered with mud, I was convinced that the practice of putting two 25-h.p. or 30-h.p. motors on one car—which would otherwise seem a waste of material and power—was not unreasonable. The full power is, of course, not always wanted, and can be regulated by the controller to suit the traffic; but it is most important to have motors that will stand extra heavy work when required and need no attention. During the year the number of passengers on all lines in Chicago was about 288 millions, or an increase of 55 millions over the previous year.

The general type of construction in wide thoroughfares is with poles planted in the centre of the road between the double track, carrying iron brackets for the support of trolley and feeder wires, and the general appearance is far from unsightly. This is specially the case when every other post supports an arc lamp or cluster of incandescents and the brackets are ornamental. Span wires are only necessary at curves and in narrow thoroughfares. The entire track construction, including rails and wires, costs about £1,400 per mile, and the car bodies, with motor trucks complete, cost about £800 per car. For a line, say, of five miles of track, with 15 cars, the power station, including building and machinery, would cost about £5,000, and real estate and car barns about £3,000—bringing the total cost of equipment to £27,000. The revenue per car mile was from 20 to 30 cents, and the total running expenses 14 to 16 cents, or on the average about 60 per cent. of revenue.

The very energetic body of the American Street Railway Association is thoroughly representative, and its members, who are all engaged in tramway work, think nothing of travelling 1,000 miles to be present at their annual conventions. At these gatherings, which occupy three or four days, original papers and reports of investigations consigned to committees at the previous meeting are read and discussed. An exhibition of manufacturers' supplies is also held at the same time, and new electric cars of all kinds are put on the town lines and run on regular service. Members practically own the town during their stay; the largest hotels are full, rooms being taken by representatives of different concerns as temporary offices. The various companies and firms in the town send in invitations to visit power-houses and works, books of tram tickets are distributed gratis, and the telephone companies place their lines at the disposal of members. Time will not allow me to do more than refer to the very pleasant participa-

* This paper, which will be discussed before the Institution of Electrical Engineers, is taken from the *Journal* of the Institution

Digitized by Google

tion I enjoyed in the last convention at Milwaukee, Wisconsin, The papers read have appeared in our own technical Press, and are consequently well known. The supplies comprise car bodies, trucks, motors, controllers, fuses and heaters, track scrapers and sprinklers, steel rails, points and crossings, compressed mica, and overhead line gear of all descriptions; everything that could be put in motion being supplied with electric current. Each member received a small choice souvenir of his visit, the gift of the newly-elected president, Mr. Henry Paine.

I now pass on to some of the questions which are absorbing attention, and to describe what I saw of the working of different systems. The directions in which improvements are sought comprise chiefly: (1) better construction of road beds and tracks; (2) better provision for the return circuit; (3) more uniform distribution of potential along the route. Further, in the power-house, the chief questions are in the driving, governing, and safety devices, the best proportion of power between engine and generator, and the problem of flywheel inertia. Beyond these there are the questions of practical and economic systems of delivering energy to cars in cities and crowded portions of towns, such as by the storage battery or underground conduit; and for long-distance transit the use of synchronous or of two or three phase motors with transmission of current by underground feeders at high tension.

Some of these questions have given rise to much discussion in America, and most of them have more or less a bearing upon the development of electric traction in our own country. It appeared to me, therefore, that I could in some measure further the progress of the industry in this country by making such observations and enquiries on the present working of tramways in the States and Canada as affected the immediate future; and I looked forward on my return to the duty, as well as the pleasure, of bringing the results of these investigations before the members of this Institution. During the summer of last year I visited the cities of Detroit and Milwaukee, and in November—on the completion of my official duties at the exposition—the cities of Toronto, Montreal, Buffalo, Cleveland, Cincinnati, Pittsburg, Washington, and Philadelphia; making also a complete examination of the electric railroad recently erected on the Canadian side of the Falls. From the officials of the various companies whose lines and plant I investigated I met with the greatest courtesy and cordiality, and the expressed wish, not only on the occasion of my visit, but at any future time, to furnish such information as might be desired.

With regard to road bed and track construction there is not much to be said, as the general conditions in America differ considerably from those in our own country. In many cities, and especially in the suburbs of large western cities, the rails are allowed to project above the road bed one or two inches, making very rough travel for other vehicles. In fact, the iron road is counted of the first importance in inducing people to live further out of town and build on the prairie, while the road for the use of ordinary vechicles is of only secondary consideration. After a few years, as property goes up in the district, a better foundation is put in, and the roads are levelled up to the metals by paving blocks or glazed bricks. Whole suburbs spring into existence in the wake of the electric tramway. Enterprise in promoting schemes is chiefly due to estate holders seeking to raise the value of their property, and it is remarkable that municipal corporations have given away important concessions for very trifling sums. These concessions after a few years generally become very valuable, and bring a good return to those who have sunk capital and taken risk; but it is now becoming more usual for corporations to look ahead and put in clauses that shall let some percentage of the profits come in for the improvement of the streets.

Practice in the western cities of Amercia is chiefly with T, flat, or step rails, spiked down to wooden cross-ties or sleepers; but on the best lines and in most eastern cities the channelled girder rail as used in England has been adopted, on account of smoother travel. less noise, and a flush road surface. The English construction of concrete foundation has been followed on some lines, using a 9in. or 10in. girder rail. The tendency now in the States is to put in very heavy girder rails (90lb. or 100lb.), spiked to wooden sleepers, placed at about 2ft. centres, which allows a good deal of spring in the track, and tends to loosen the bond contacts. Some 72lb. channel girder rails I saw in progress of laying had grooves 1⅛in. wide by 1in. deep. The height and base both measured 6in. There was first an 8in. foundation of concrete, upon which the sleepers (6in. by 8in.) were laid at 2ft. 3in. centres, and then grouted in. Sand was then tamped round the base of the rails to the depth of 2in., upon which the paving blocks were laid. The points and special work were of cast steel.

The question of returning the current direct to the power-house with as little leakage and loss in voltage as possible, is one of the most important in street railway problems. Excluding for the moment insulated returns, the paths open for the return current from the cars to the power-house are (1) by the rails and return feeders; (2) by supplementary wires; (3) by the earth; (4) by metallic pipes and cables laid in earth. The return feeders include not only those cables connecting the nearest point on the rails to the generators in the power-house, but cables brought in from more distant points of the line, as the configuration of the same and the load may require. In this matter everything depends on the position of the power-house with regard to the route of the line. The primary object in their use is to lessen the voltage losses at the distant portions of the line; but in some districts their use has been largely extended, in order to prevent electrolytic effects on gas and water pipes. The remedy for the latter is clearly to provide a metallic return of ample conductivity, and while on modern lines improved bonding has done much to effect this, the addition of return feeders has had the desired effect in older and badly-bonded lines. In Cleveland, Ohio, for instance, I found a very extended use of return feeders, and I was informed by Mr. Charles W. Wason, vice-president and electrical engineer of the East Cleveland Railway Company, that he had resorted to their use entirely on account of electrolytic troubles with the water-pipes of the city, with the result that the action ceased, and in addition about 25 per cent. of the voltage was saved. Some idea of the advantage of a saving in volts, apart from the consideration of speed in cars, can be gained from the fact that the current reached 3,000 amperes, and that for, say, 50 volts lost on the line every 1,000 amperes means a continuous loss of 70 h.p. The return feeders in this city are carried overhead, and are connected by riveted joints to the rails at about every 500ft. In Buffalo, also, I observed an extensive use of return feeders, carried underground with the outgoing feeders within the city limits, but overhead further out.

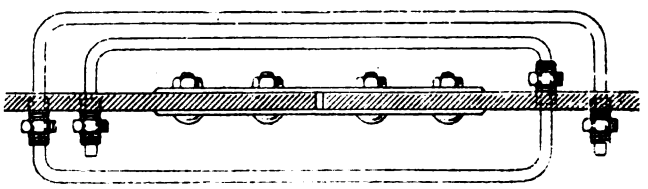


FIG. 1.—Bonding Nipple.

Coming now to bonding, I have seen many different specimens of this work, and have some samples here to-night for the members' examination. One form of bond joint, Fig. 1, consists of a steel nipple bored to fit the bond wire, and tapered and slotted at one end. This screws into the rail, and the nut, screwed up, tightens the wire in the nipple,

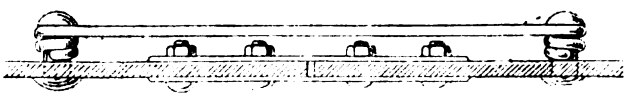

FIG. 2.—Rivet and Soldered Bond Wire.

and the nipple in the rail. This was introduced by Messrs. Stern and Silverman, of Philadelphia, and is used on the lines of the electric traction company of that city, the bond wires being passed two or three times through the rail outside the fishplates to obtain the necessary conductivity. There are still many very imperfect bonds in use, such, for instance, as that with copper or iron rivets and soldered bond wire, Fig. 2, of which I have a specimen here. In heading the rivet

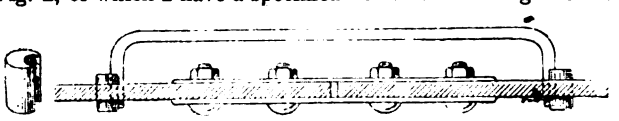

FIG. 3.—Channel Pin.

the soldered joint is frequently loosened and the bond rendered useless. The channel-pin bond, Fig. 3, of which I have a specimen here, is in very extensive use; but a great defect in this device is that it cannot be riveted or made to completely fill the hole, and corrosion takes place in the interstice. The channel pin is used for the double bonds on the Lynn and

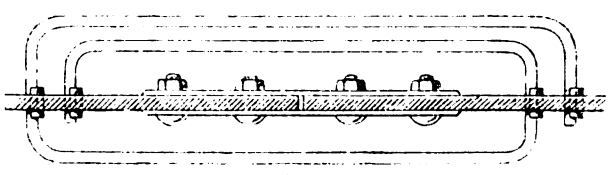

FIG. 4.

Boston line, as shown in the illustration, Fig. 4. Another bond is taper spring steel cap, Fig. 5, which is fitted on the end of the wire and driven into a hole in the web of the rail slightly less than its own external diameter. A similar bush joint, but formed as a sleeve or socket, has been in use some time on double bonds, as in illustration, and promises well, Fig. 6. A considerable improvement consists in making the bond wire in one piece, with shoulders for riveting formed at

Digitized by Google

each end on the wire itself. This device (shown in Fig. 7) is due to Mr. McTighe, of New York, and has been very largely used. The advantages of this plan are that clean, watertight, and airtight solid metallic joints are obtained, and that the bonds can be made of any size wire. Mr. McTighe prefers to use these in short lengths of 12in. inside the fishplates, instead of the usual length of 30in., thus saving 40 to 50 per cent. in bond resistance. The short bond cannot be fixed to the web of the rail on account of the fishplates, but is either attached to the tread or the base, the latter being the better point of attachment, as the bonds are soon worn away when on the tread. This bond, however, sooner or later becomes loose, owing to the difference in the coefficient of expansion of copper and steel, and this being followed by galvanic action, the resistance, which at first is slight, rapidly increases at the joint. Some provision by which solder could be run in might add to the certainty of this joint, the ductility of the solder taking up the unequal expansion and contraction.

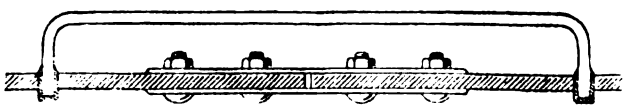

FIG. 5.—Taper Spring Cap.

Some of the older lines in the States, laid before the value of good bonding was appreciated, show an enormous loss of voltage from this cause. I was informed that on an old line in Richmond, Virginia, the bonding was done by No. 6 iron wires, and the same bonds used for a recent extension of 2½ miles, with the result that of 500 volts put into the line not more than 210 appeared at the distant end. The matter was investigated in consequence of bad working, and good copper bonds substituted for the iron wire, with the result that the loss was reduced to 5 per cent.

Bond wires are subject to corrosion by electrolytic action, especially in alkali soils. The wires consequently become thinner and conduct badly, and some of the current is shunted round the joint to earth, thus increasing the corrosion. Again, when the wires get very thin they become heated, and fuse, thus throwing extra load on other feeders. I was informed that the action was prevented by painting the wires, or coating them with shellac and asphaltum. The section or number of bond wires has, of course, to be increased nearer the power station.

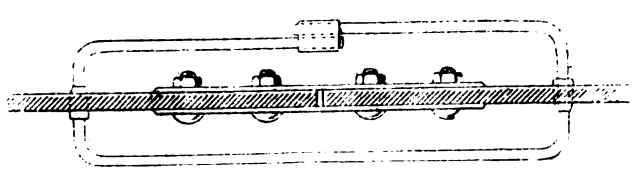

FIG. 6.—Split Steel Sleeve Bond.

The conductivity of the return circuit has been increased on some lines by the use of a supplementary wire, which is usually of bare copper §in. or ½in. diameter, laid along the centre of the track. Cross-connections from all bond joints are made by copper wire twisted and soldered to the supplementary wire, and on double tracks the supplementary wires of each track are connected every 30 yards. I saw new lines being laid with these wires in Chicago and Detroit, but I have also seen lines freshly opened up where the supplementary wires were considerably corroded, and was informed that their life was about two years. There were so many joints in the system, the wires used were so small, and were of such poor conductivity in comparison with a well-bonded rail, that the expedient appeared to me to be temporary and unreliable. In fact, I gathered that one of the chief uses of the wire was that its presence allayed to some extent the anxiety of the city authorities, otherwise harassed by water and gas pipe corrosion.

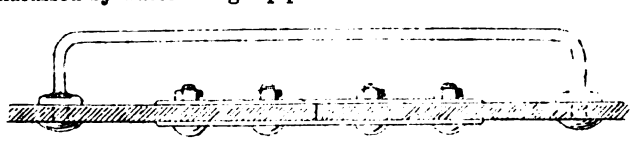

FIG. 7.—Bond Wire with Shoulder Riveted in one piece.

I next come to the earth as a return. I found that earth connections were made on most lines at their lowest points and at the power-house. Such connections were made by sinking old car wheels or driving rails or pipes in moist earth, and making as good a connection therefrom to the rails as possible; but, from all I could learn, not much reliance was placed on such returns. The extremes of weather no doubt have something to do with it, as hard dry earth is a bad conductor. Even wet mud in comparison to the rails is a poor conductor, as is evidenced by the brilliant arcing at the wheels of cars running on a muddy rail. In the *Street Railway Journal* for last December, some tests by Mr. James D. Rostron, chief engineer of the Union Railway Company, of Chester, Pa., bearing upon the conductivity of the earth as a return were published. Mr. Rostron obtained an average of 285·5 amperes through the track and supplementary wires, 12·8 amperes through the city water-mains, and only 0·51 through the earth-plates sunk in creeks. If this is confirmed by further tests, it shows that the conductivity of the earth as a return is not high, but depends upon the presence of metallic conducting matter within it. While in Chicago I made some tests to ascertain the approximate conductivity of the earth, and the difference of potential required to force current through pipes not metallically connected to a circuit. I laid some lead and iron pipes in earth, and at 1½in. distance above them I placed two iron plates as electrode, 6ft. apart. Each plate offered 20 square inches of surface, and the current passed partly through the 6ft. of earth from plate to plate through clay,

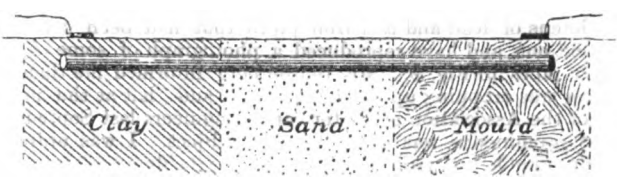

FIG. 8.

sand, and mould, and partly through 1½in. of earth at either end (clay and mould), and along the pipes, Fig. 8. I expected the resistance of the latter part would be almost nil, and, as I had 120 volts at disposal, I first put a resistance in series of four 105-volt lamps in parallel. I found, however, that the earth resistance was far more than I anticipated, and I removed three lamps with very slight increase of volts on the remaining one. The current was then half an ampere, and the earth absorbed 20 volts. A few days after, I obtained current from a 200-volt circuit, and put the four lamps on again. I then had 2½ amperes, with 100 volts absorbed by the earth. After keeping the current on for two weeks, the pipes were taken out, and were found to have a pitting of white scale in places at the negative ends. The scale was in white lumps, which, upon being scraped off, revealed the starting of little holes about $\frac{3}{32}$in. diameter. This proved that some of the current, if not almost all, had passed by the pipes through the 3in. of clay and mould. While I attribute this high earth resistance to the clay, which had set hard, I am still of opinion that the earth has more resistance than is generally imagined, and that to attract current in anything but very minute amounts from a well-bonded rail to earth requires special conditions—such as deeply sunk plates, metallic connection to pipes, the ground saturated with moisture, or an excessive density of current in the bonds. I was informed by Mr. C. H.

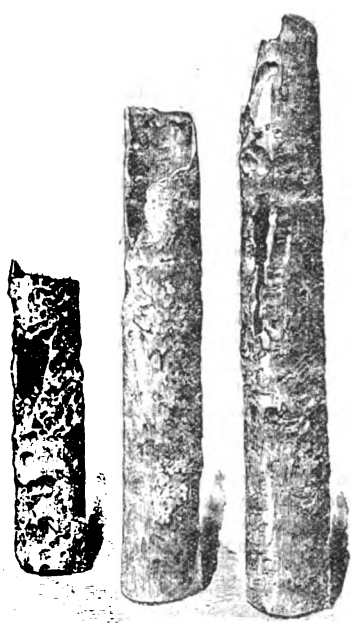

FIG. 9

Morse, the city electrical engineer of Cambridge, Mass., that in some tests he made at Saginaw, Mich., for the gas company there, he was surprised to find that pipes were eaten away in two or three months under a return current which did not exceed 500 amperes. The soil was, however, very moist clay, and the rails were connected to earth-plates.

This leads me to the question of the use of city water-mains and gas-pipes as return conductors. At Milwaukee, Wisconsin, where this was first brought under my observation, I was informed by the city engineer, Mr. G. H. Benzenberg, that considerable difficulty had been experienced. City water-mains and service pipes had become corroded in from two to three

Digitized by Google

years, the action being most marked near the power stations. An attempt was made by the passing of an ordinance to stop the tramway companies connecting their rails to any pipes whatever; but the matter had gone too far, and the benefit to the latter companies in reducing volt losses by so doing was so marked that the practice was still carried on in spite of this ordinance. The matter was at length remedied by obliging the companies to make good connections to the water-mains at the nearest points to the power-house where the current left the pipes, such connections being taken right on to the switchboard return. The point proved was that pipes were affected at points where the current left them, like anodes in an electrolyte, and that protection could be afforded by putting a conductor instead of the electrolyte to earth. In this way pipes in an affected district could be thoroughly protected, but at considerable expense. It was evidently better to put such conductors to the rails direct, and not connect to pipes at all. I saw several specimens of lead and cast-iron pipes that had been corroded and cut out, and have reproduced a photograph of some of the larger pipes in Fig. 9. Mr. Benzenberg informed me that the matter was cropping up in several cities, and that at the meeting of the Association of Waterworks Engineers last September great prominence was given to this subject. I was unfortunately unable to visit Boston and Cambridge and see the extensive electric tramway systems and the enormous power-houses there, but partly by communications with Mr. Morse, and partly from Boston engineers who visited the exposition, I was informed of some of the experience gained on these points in those cities.

The amount of return current to deal with can be imagined when it it is known that the West End Railroad Company have an output of 12,000 h.p. This is distributed from three stations, of which the one at East Cambridge alone has an output of 6,000 amperes. Considering, also, that of 270 miles of track more than half is of 56lb. and 70lb. rails, laid years ago, and either bonded indifferently or not at all, it is not surprising that pipes and cables which were metallically connected to the rails in places should be affected. The information I have from authentic sources is that the water and gas mains and lead-armoured telephone cables suffered to a very great extent. The Bell Telephone Company tried earthing their cables by connecting them to lead plates buried in manholes, but this afforded no protection from the very heavy currents passing.

A curious experience was gone through in this city in reversing the direction of current. The supplementary wires resorted to as a means of increasing the conductivity of the track became corroded to such an extent that when a car passed an affected section a difference of potential was set up between rails and earth sufficient to cause shocks to people and horses. This effect was so great towards the end of the year 1891 that the West End Railroad Company reversed their current, making the rails positive and the trolley wires negative. The current then left the station by the earth connections, including all piping in the station, and the condenser pipes were attacked. Other troubles arose at fresh points where the current left the city pipes to get on to the rails, and to obviate these the current was again reversed, making the trolley wires positive again. The action was then noticed in places near the power house where the current left the pipes, and this was overcome by making heavy copper connections to the pipes in these places, and carrying the same to the negative poles of the generators in the power-house. It was also found that gas-pipes had to be treated in the same manner, and soldered connections were made between gas and water pipes in all large buildings and in places in the streets. Where the return currents reached 12,000 to 15,000 amperes the ground along the track was found to be heated, and return feeders from heavily loaded points had to be used. These were tapped down near the station to underground pipes as it was found that if this was not done the pipes entering the station were at a difference of potential sometimes as much as five volts—sufficient to heat an iron wire between them, with consequent danger of fire.

Mr. Morse, in a comprehensive paper on this question before the New England Waterworks Association at Boston, Mass., in January, 1893, describes having tried covering pipes with cracked stone, and in muddy places bedding them in cement as a protection; but this was costly, and of no use unless done completely over the whole pipe system. The trouble with electrolysis in this city I take to be due to the exceptionally large outputs and indifferently bonded rails. The city has purchased experience at heavy cost, but which has been of benefit to others. The adoption of return feeders and good bonding on later lines, with freedom from these troubles, has been one result. At the same time the congested condition of current-density has raised the question of some other means of distributing current to cars. One method about to be tried in Boston and Cambridge is the three-wire, or zone system. The rail or earth return would then be the neutral wire, and the sections of trolley wire would be alternately positive and negative. The section of the trolley and feed wires within a circle of, say, one mile of the power station would be at 500 volts positive potential, and the outer sections 500 volts negative. Further, this section might be again divided into half or quarter mile zones, or further subdivided, thus practically preventing any flow of current in the earth. By this means the potential and volume of current would be distributed more evenly over the circuit, and there would be less concentration of current at power-houses. The current would return by the insulated feeders. On the other hand, there would be a current flowing through the rails or earth from the cars on one section to cars on another; but this would supply power to twice as many cars as on the two-wire system. On rare occasions, if all cars happened to be banked on one section or a set of sections at one potential, the action would be like a two-wire system, and the current return by rails and earth to the station. The spark, on passing an insulated junction between trolley wires of opposite potential, could easily be deadened by a small high-resistance shunt across the break. The general advantage of such a system cannot be pronounced upon until it has been tried; but as far as the return current is concerned, it appears to offer considerable relief. I should mention here that in Boston the experiment was tried of welding the fishplates to the rails, thus making a permanent and reliable electrical joint. The Johnson Company, after obtaining good results on 3,000ft. of experimental track, were empowered to weld 16 miles for the West End Street Railway Company, and during two years the rails have shown no tendency to buckle. During this winter, however, I learn that the rails have broken into sections of a few hundred feet, due to contraction, the fractures always occurring near the weld. I believe, however, that this is the right method, and may still be modified to give successful results. The bond should be made outside the fishplates, allowing a loop for contraction, and the poles of the welder should be arranged to distribute the heat gradually from the weld, and so prevent abnormal strain of the metal. The absence of dissimilar metals in the joint ensures its permanency as long as the rails itself lasts, both as regards local action and expansion.

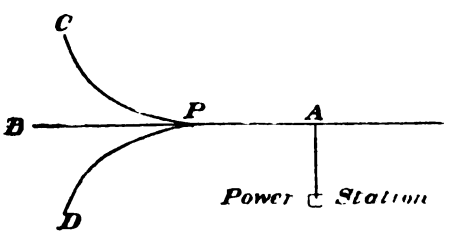

FIG. 10.

Reviewing the circumstances attending electrolytic action, as far as I have been able to gain information on the spot, I find that these troubles have chiefly been traced to insufficient conductivity at the rail joints, and to the want of proper return conductivity in the shape of feeders. When traffic on the lines increases, or extensions take place, and the increased power is drawn from the same supply station, either the bonds must be increased in sectional area (if they have not been put in at first of sufficient size for ultimate demands), or return feeders must be run to relieve the bonds, otherwise the consequence will be that the current will be crowded out of the rails into the earth. This is what has actually taken place on some systems in the States, and the current has been allowed to take its own course until the heating of rail joints and bonds has drawn attention to the want of conductivity. This crowding out occurs on the main or trunk lines, into which several branch lines converge. On simple lines, or those from which no branch lines radiate, it is less liable to occur, as even with an excessive volt loss per mile the density of current is well within the capacity of ordinary single bonds. Take, for instance, a line of three miles of double track between A and B, Fig. 10, and consider it first with no branch lines. Say we have a three-minute service of cars, and the average speed, allowing for stoppages, is 7½ miles per hour. The cars will then be three-eighths of a mile apart, and there will be eight cars on each track. With two motors per car the current will be about 25 amperes at maximum speed; but some cars will be starting, and using 100 amperes, and we may take a time average right through of 50 amperes per car. The maximum current returning to the power station from A will then be 800, and the maximum at B 100 amperes. The resistance of copper bonds varies according to method of bonding, length and size of bond wire, and whether it is double or single. Per mile run of rails the bonds may be from one-sixth to twice or three times the resistance of the rail. Taking a 70lb. rail with low-resistance bonds, say, of No. 000 gauge, 12in. long, and fixed double, we shall have the resistances per mile of rail 0·0344 ohm, of bonds (176 to the mile) 0·0056 ohm—total, 0·04 ohm, or 0·01 ohm for the double track. The voltage loss will therefore be one volt per mile per 100 amperes. Working this out for the varying strength of current on different portions of the return, we have a loss of 10 volts on 1½ miles from A to P, and four volts on an equal distance from P to B—total, 14 volts. Suppose now a branch line is laid from P to C, also of 1½ miles, with cars at same speed and same rate

Digitized by Google

of service. This will then absorb four volts, but the loss between P and A on the trunk line will be increased to 19 volts; and if another similar branch, P to D, is added, the loss on the trunk line becomes 28 volts, or a total of 32 volts on the whole. When it is considered that with a theoretical continuous rail without bonds this loss is only reduced by five volts, it will be seen that to prevent waste of energy, quite apart from reducing current-density, we must connect return feeders to the rails on the trunk line. Now, considering the current-density, we have in the trunk line, when the two branches are in operation, a current of 1,300 amperes at P and 2,400 amperes at A. The maximum current per rail is therefore 600 amperes, and this on seven square inches gives a density of 86 amperes per square inch of rail (equivalent to 510 amperes per square inch of copper). This could be increased four or five times before any sensible rise of temperature would take place in the rail; but, considering the bonds, whose sectional area per rail is 0·262 square inch, we find we have a density of 2,290 amperes per square inch. It would probably take very little increase of current beyond this to cause heating of the bonds and crowding out of current into the earth; and yet the bonds on many lines in the States have less sectional area than the one cited, and the currents are from twice to four or five times as great, producing far higher densities in the bonds than they can carry. I am convinced that this is the cause of most of the electrolytic troubles in the States. Trunk lines into which a number of branch suburban lines feed are frequently of considerable length, and cars necessarily move slower in consequence of their accumulation on one line. Not only on account of the number of cars, but also because of their slower speed and frequent restarting, the current put on to the rails is very much increased, and the density in the bonds becomes far more than they can carry. We have seen that it is not a question of resistance or conductivity of the bond, as the voltage loss beyond that on a perfectly continuous rail is only increased by about one-sixth of that lost on the rail, and therefore the increasing of the conductivity confers no appreciable benefit so far as reducing voltage is concerned. The question is one of sectional area of bond with reference to the ultimate maximum current it is expected to carry, and this, I think, should not exceed 2,000 amperes per square inch. The sectional area of the bond refers as much to those portions in contact with the rail at the joint or joints, as to that of the single or double bond wire itself. I cannot leave this portion of my paper without a tribute to the pioneer work and enterprise of our transatlantic cousins. They meet every difficulty squarely in the face, and in spite of all obstacles "get there all the same." Our designs must necessarily comply with more conditions than are exacted in America, but when our difficulties have been the same our friends have generously been ever ready to impart their experience.

I will only touch upon one of the Board of Trade regulations—viz., rule 7—similar to which is rule 9 of the draft regulations for underground electric railways. In its draft form rule 7 exacted that the original or recorded resistance of the return should be maintained constant, with a maximum allowable increase of 15 per cent. In its amended form the same idea is carried out, but the element of current strength is included—namely, the product of resistance with current—that is, the difference of potential between extreme ends of the line—and this must not exceed seven volts. The framing of the rule, I take it, was aimed at securing a low density of current in the rail, thus preventing the crowding out of which I have spoken, and placing the pipes of gas and water companies beyond all harm. It seems to me that this end is not altogether accomplished, because with a given difference of potential, however low, it is possible to have a very high density in the bonds, with a very low one in the rail. In other words, under complete compliance with the rule the bonds may be carrying far too high a density and shedding their current into the earth. Referring for a moment to the example considered above, a heavier rail might be laid with bonds of less sectional area and still not alter the difference of potential at the ends of the uninsulated return. A 90lb. rail would have 0·0268 ohm per mile—that is, 0·0076 less than the 70lb. rail—and this difference could be made up of smaller bonds of less carrying capacity. By using single bonds of No. 00 gauge (0·104 square inch section) instead of double of No. 000 (0·131 square inch section), this is obtained very closely, and we have the resistance per mile of rail 0·0268 ohm, of bonds 0·0142—total, 0·0410, or 0·01 ohm, for the double track, as before. The difference of potential at the ends of the uninsulated return for the same currents is therefore unchanged, but the densities are very different. That in the rail is reduced to 66 amperes per square inch (equivalent to 400 amperes per square inch of copper), while that in the bonds is increased to 5,760 amperes per square inch—nearly three times more than the limit I alluded to. Some of this density is relieved, of course, by the conductivity of the fishplates, but this is of such a variable and unreliable nature that it should not be reckoned upon. Density, of course, can and should be relieved by return feeders, and these would be necessary on most lines of any extent to keep the volt loss within the required limit; but even with return feeders and low density in the rails I have shown that there might still be too great a density in the bonds if these were not of sufficient section. Further, it appears to me that a limit of volts per mile would be equally effectual and more workable than a certain limit for lines of all lengths and traffic.

Having endeavoured to put before you the results of my observations, I may say that I am convinced that bonds should be of sectional area proportioned to load, which will materially lessen cost of return feeders; and secondly, at points on the rails chosen with regard to load, return feeders should be connected of such section as to relieve the density of current in the rail. By return feeders I do not mean supplementary wires or connections to water-pipes, but metallic conductors either above or below ground, not necessarily insulated, but connected direct from the rails to the power station. Supplementary wires are of no use unless increased in section as the current increases, so as to keep an approximately constant density, and this I have never seen done; while making connections to water-pipes is a makeshift at best, and one that shows a want of good design. I believe that by designing the return circuit of electric tramways in the manner I have indicated we shall keep clear of electrolytic troubles upon gas and water pipes, and ensure an unhandicapped career for electric traction in this country.

I now come to systems in which the return is insulated from earth—namely, those using the overhead double trolley and the underground conduit. I was much interested in the double-trolley system working in the city of Cincinnati, Ohio, and wished to ascertain whether the insulation from earth was well maintained, and of sufficient benefit to warrant the use of such a system. I received the greatest courtesy during my stay in that city from Mr. George Hornung, civil engineer; Mr. H. P. Bradford, of the Cincinnati Inclined Plane Railway Company (using single trolley); Mr. Kilgour, of the Consolidated Street Railway Company (using double trolley); and Mr. Wm. J. Clark, of the General Electric Company, with whom I visited the power-houses and inspected the lines. I shall not easily forget my first impressions of double-trolley working, as I passed through Fourth-street to Fountain-square, in the busiest part of this city, on the morning after my arrival: cable cars, double and single trolley cars, and horse cars followed each other in rapid succession, often on the same track; but the most startling thing was the immense amount of trolley and span wires suspended over the roadways, with all the necessary adjuncts of insulators, guard wires, frogs, and separators. I watched several of the double-trolley cars rounding curves, and observed that the trolleys frequently jumped off the wires, and that the conductor on the car had to keep his eyes on the trolleys and steer them with the cord on passing curves. A good deal of extra complication was due to the presence of single-trolley wires along double-trolley tracks, and the necessary use of span wires in the narrow streets of the city. Out in the suburbs, however, the double-trolley construction was seen to better advantage, as the wide roads allowed for centre-pole construction. The rumour prevailed in other cities that the double-trolley system was on its last legs; but, so far from that being the case, I found that the Board of Affairs of the city had just granted the company powers to lay 50 additional miles of double-trolley track, the mileage then in operation being about the same in extent. No doub the rumour arose from the fact that this was the only city in the States (with the exception, I believe, of a small line at Rochester) that employed the system, and the history of its rise in Cincinnati was remarkable. The first to be put down was a single-trolley line, which was opposed by the telephone company on the ground of interference. Litigation resulted in favour of the latter company; but the tramway company appealed on two or three judgments to higher courts, and eventually got a verdict in their favour.

(To be continued.)

THE CITY ELECTRICAL INSPECTOR.

Mr. A. A. Voysey, who on Tuesday was appointed electrical inspector to the City Commission of Sewers, is 30 years of age. He learned mechanical engineering at the Barrow Steelworks, and studied under the late Prof. Lant Carpenter at the School of Electrical Engineering, Hanover-square, where he passed all his examinations at the head of the list. Leaving there, Mr. Voysey became connected with Messrs. Siemens Bros., where he was engaged under Mr. Jacob, the chief electrician. Subsequently he joined the firm of Callender's Bitumen Company, and for them he laid down the important low-tension distributing systems in Liverpool and Birmingham, and also carried out similar work in London and in Denmark for the same company. The largest work was, however, executed at Liverpool and Birmingham.

GISBERT KAPP.

It is an interesting custom with Englishmen to "speed the parting guest." In connection with this custom, a few of the friends of Gisbert Kapp will appear at a function to be held at the Whitehall Club in a day or two, consisting of a dinner and a presentation to the gentleman who is leaving us, whom, indeed, till recently we had not looked upon as a guest, but as one of ourselves. It may be said at once that the one great reason for Mr. Kapp's decision to leave this country has no connection with business at all. It is with great reluctance that he breaks away from friends who have grown up around him contemporaneously with the growth of the industry to which he is so bright an ornament, and to the progress of which he has so largely contributed. From almost the earliest days of the modern electrical engineering development Mr. Kapp has been connected with it. We well remember a remark of Mr. Crompton's, with whose firm Mr. Kapp was then connected. "He is a first-rate engineer," said Mr. Crompton, "but knows very little about the electrical part of engineering. It will be our business to introduce him to that, and he will soon pick it up." The foresight of Mr. Crompton has been completely justified by the lapse of time. Not only did Mr. Kapp soon pick up all that was then known about electrical engineering, but he soon pushed ahead into fresh fields and pastures, and from that early period has stood in the fore-front of all those whose work and investigations have reduced electrical engineering to an acknowledged industry, and separated and defined it as a distinct branch of engineering. At the time Mr. Kapp took up the practical work of electrical engineering the rule of thumb was prevalent—indeed, it was the only rule that reigned supreme. It was largely his work that enabled us to write a specification — to indicate and foretell the results a definite piece of apparatus should give. Gradually order was evolved from chaos, and we contend that much of the order is due to the work, the energy, and the ability of Kapp. The papers he has read and written are the classics of the subject. They are probably consulted by practical men more than all other papers and books combined. Others may have written more, but the writings mostly savour of pure scholasticism, and are practically useless. Mr. Kapp, with one or two others, has been, and is, the guide, philosopher, and friend of the practical man. And this is the man his friends meet and delight to honour, though it is to bid him farewell. We lose a man who had largely imbibed English thought, whose brainwork was quickened by contact with our best, whose labours have been among us and of us, and to whom we pointed with some national pride as a growth of England's possibilities. The incentive to his work was from England, and the results we claim for England. In the heyday of his experience, he is to give the whole of his unsurpassed powers to his native-speaking race. Our loss is their gain; and though we as a nation are somewhat uncouth and uncommunicative, we are sure that before Mr. Kapp leaves these shores which he has so long called home

Digitized by Google

he will find that there is a depth of feeling among us, and a sincere admiration for all that is good and noble and honest, that he will, like many before and many who will come after, realise that only under exceptional circumstances can the depth of England's regard be duly gauged. Many of us will be unable to meet Mr. Kapp at the function to which we have referred, but we can assure him that the gentlemen who do meet him will all inadequately express the regret that is so general at his leaving us. The regret is the keener in that we know the cause to be chiefly due to the health of his helpmate, and we shall all unite not only in heartily wishing him every success in his new sphere, but that the change will bring brighter sunshine into his home and into his daily life. .

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

"OUR REVIEW OF REVIEWS."

SIR,—Sam suggested, you will remember, that I should make it hot for sheet lightning, and now I will fulfil my promise to do so. Before, however, making it very warm, I will refer to It of July 5. Of course "Gas Meter" occupies the first pages of this rag. Opening with the Tower Bridge, "Gas Meter" fully justifies his pseudonym by puffing in a reprint of a circular issued broadcast the gas lighting of the bridge as carried out by a firm of gas engineers. A firm of wine agents then receives attention. Perhaps "Gas Meter" is going to make electrical experiments with the wine—give it age, for instance. Well, I guess he can give it age—and body, too. Then he writes something about gas, of which, having such a lot himself, he tries to inflict a little upon others.

But who is Mr. Ohen? What will Mr. Chew, of Blackpool, think of this mutilation of his name? But, of course, he is not likely to look at It.

Chestnut, jun., discourses in the financial padding from the daily papers on the Wellsbach (*sic*) lighting. Is it not time that he learned how to spell? Surely Frenchmen who have lived in England for some years should understand a leetle Engleesh. I once knew a Frenchman who resided here for 12 years, and yet he did not know a well's back light from a duck's back. Chestnut, jun., then laments that the House-to-House Company does not pay a half-yearly dividend on its preference shares. Surely Chestnut, jun., who was, and I believe still is connected with the company, knows perfectly well the reason why it does not, and also why no dividend is forthcoming on the ordinary shares. But is it not rather nasty on his part to say to his brothers that "this is a very poor financial operation on the part of its Board?" Chestnut then hears for the first time, what you published about two months ago, about the conversion into a limited company of a firm of ventilating engineers.

In "Our Review of Reviews" "Faddist" actually says of its little schoolboy sister, the *Cable Gazette*, that it has "the usual sneer at parochial management." And this, too, after having loved her so well! Poor little baby; dear, sympathetic "Faddist"! Its idea of wit, It says, is to leave out the nots. "Lamplighter" will have to go to school again, too; poor little boy, talking about electrical energy at so much per 1,000, as if it was gas. But can you expect a "Lamplighter" to know of anything other than gas?

I found a copy of It in the train bearing the date of July 12. Don't know whether this was an advertising dodge—if so, it was not so good as that practised by the *Cable Gazette* on the *Financial Times*, which you recently exposed—or whether somebody had seen through It and become disgusted. When I reached Sam's house he said, "What a lark. 'Gas Meter's' been stung by a bee." "I don't know so much about it," I replied. "It looks as if he had been hugged by a bear." Sam could not see it for a moment, then he exclaimed: "Why, you mean the lightning express railway service which 'Gas Meter' now hears of for the first time." Then we both laughed. "Gas Meter" next quotes something from the *Cable Gazette* about electric heating and cooking, and says "this sort of things provokes laughter." Of course it does. Ha, ha, ha! Poor little sister, in for it again. Ha, ha, ha! Next he remembers in his "student days an electric foot-warmer being brought into the works to be tested." Evidently he has not yet ceased attending school. Ha, ha, ha! I really cannot help laughing. Fancy an electric foot-warmer in "Gas Meter's" student days of any time ago! Ha, ha, ha! This reminds me of a remark made by one man to another when passing down Bishopsgate-street the other day. He said: "Blessed if these lamps are burning right." "No, they ain't," replied the other. "You should 'ave seen the electric lamps here in '49; they was stunners." "Gas Meter," it seems, finds every week greater difficulty in padding out the space in this little sheet. He manages this week to fill up with such irrelevant items as the speed of torpedo boats, a cutting from a daily paper about the twenty-fifth anniversary of the Broad-street cable clique, and two columns about matters *only one hundred years old!* "Gas Meter" winds up by discovering for the first time that there are such motors as oil-engines.

"Faddist," in "Our Review of Reviews," desires to be once more friendly with the *Cable Gazette*. Isn't he a turncoat? He kisses his little baby sister, and says, "Be friends, ciss—won't you?" Then he tries to launch forth at the *Electrical Review*, which criticised Mr. Hammond's paper on electric traction. The *Electrical Review* was quite correct in its statements on the subject, and "Faddist" does not like it. But had "Faddist" anything whatever to do with it? Of course not.

I feel quite flattered by "Faddist's" reference to myself. He actually takes without acknowledgement a block from the *Electrical World* of the 2nd June to illustrate his own qualities, demonstrating that there is a close connection between lightning and a donkey. Good old "Faddist." It is suggested that I suggested there was an understanding on the part of It and preceding occupants of Its offices. I would never dream of believing It had any understanding. Chestnut, jun., and "Lamplighter" manage to pad out the remaining columns with a lot of stale matter that you have previously published.—Yours, etc.,

JOHNNY.

Timbuctoo, July 18.

GAS v. STEAM FOR CENTRAL STATIONS.

SIR,—My attention has just been called to the article in your issue of the 6th inst., and as you are good enough to invite discussion on the subject to which it refers, I beg to offer the following remarks:

Preliminary Installation.—An ordinary set of gas plant for 160 i.h.p. should not cost more than £500 erected, including builder's work.

If the estimates you give refer to the place I believe they do, the £732 for gas plant is due to the fact that the engineer included a much larger gasholder than usual—viz., 20ft. diameter by 10ft. deep, as part of the provision for additional power when required. Clearly it would be wrong to compare this with steam plant, which includes no such provision.

A six ton traveller for the gas plant is put at £300, and a similar one for the steam plant at only £200.

The buildings are put at £2,000 in each case, but with the gas plant there would be no costly chimney shaft.

The above items affect the 10 per cent. for contingencies and the interest on capital outlay.

Complete Installation.—If this plant is for the place I suppose it is, the engineer for reasons of his own made it include *three* gasholders, each 20ft. diameter by 10ft. deep, and *nine* generators and *nine* sets of scrubbers, etc. In the usual way, one holder of the above size and five generators, etc., would be amply sufficient. For some years past Messrs. Crossley have used one generator to serve about

Digitized by Google

300 i.h.p., and other examples of large powers could be given.

The effect of having three separate gasholders not only increases the initial outlay for plant, but adds materially to the ground space and builder's work.

Working Expenses.—The estimates for gas power are based on anthracite at 24s. a ton, whereas gas coke can be used, and the local price of this is probably under 10s. a ton. There are several gas plants working well in the North with coke, and it is hardly fair to gas power to take its fuel at 24s. against 6s. for steam.

If anthracite is used, the consumption should be taken at 1lb., not 1½lb., per indicated horse-power per hour, in engines of the size selected.

The cost for water for gas power is wrongly stated, as 500,000 gallons at 7d., per 1,000 = under £15, not £150.

The repairs and maintenance are taken as higher for the gas power than for steam power, whereas the contrary is guaranteed.

No mention whatever is made of the fact that the stand-by loss in gas generators is much less than in boilers. The loss in one generator of 300 i.h.p., when standing several hours with a fire in it, is under 8lb. per hour.

As these erroneous estimates have been published without explanation, I venture to suggest that it will be only fair to the engineer that his report should be published also, as in this he may have given some explanations which it would be well for your readers to know of.—Yours, etc.,

J. EMERSON DOWSON.

SIR,—In your issue of the 6th inst. we notice on page 10 tables giving the estimated comparative costs of an electrical plant driven by steam or gas engines. Some of the figures in connection with the expenses of the gas-engines seems to us to require revision.

In the first place, you will find that the figures bracketed together as being the cost of the Dowson plant, gas-engines, dynamos, water-tanks, and overhead traveller, amount to £3,042, instead of £3,092, as printed. In comparing the figures, it seems strange to us that the cost of a six-ton overhead traveller in connection with a gas-engine should be £300, whereas the same article when used in connection with a steam-engine can be bought £100 cheaper. Assuming the cranes to be the same, it seems a little hard that in the case of a gas-engine such an invidious distinction should be made!

The price of the two Crossley gas-engines of 35 nominal horse-power is also rather high, as we consider that engines of this size could be delivered and fixed under ordinary circumstances for £1,000. We also note that £100 is put down for water-tanks, piping, and connections, which would be included in the £1,000 above mentioned. The cost of the Dowson gas plant also seems to us rather high for this power; but leaving this figure alone, our estimated capital of the gas plant would be as follows:

One Dowson gas plant, including one gas-tank, two generators, scrubbers, etc., fixed, taking your figure	£732
Two Crossley gas-engines, each of 35 nominal horse-power, delivered and fixed	1,000
Two Siemens dynamos, as per your figure	710
One six-ton traveller	200
Electrical instruments, etc., as per your figure	1,700
Distribution service, etc., as per your figure	1,200
Central-station buildings, as per your figure	2,000
Contingencies, etc., 10 per cent.	754
	8,296
Add for land, etc., as per your estimate	1,000
Total	£9,296

This brings the cost of the plant worked by gas-engines to £64 less than the estimated cost of the steam-engine and plant.

Then again, in the third and fourth tables giving the working expenses for the two plants, you give the consumption of anthracite in our engine as 1½lb. per indicated horse-power per hour. This is 50 per cent. higher than it need be, as in making gas on such a large scale you will be quite safe in allowing a consumption of 1lb. per indicated horse-power per hour. This would considerably modify your figures, and would bring down the total of Table No. 3 from £1,116 to £1,102. This you will see is also less than the corresponding figures giving the estimated cost of working the steam plant. By making the same reduction in the amount of fuel used in Table 4, you will arrive at a total of £4,240 instead of £4,440.

We think, therefore, that when all these alterations are made, the gas-engine-driven plant will, on the whole, be found to be the cheaper of the two.

Another very important item which appears to have been left out in Table 1 in the case of the steam-engine plant is the cost of a chimney; and we see that for central-station buildings £2,000 is allowed both for the gas-engine plant and also for the steam plant. If the £2,000 is supposed to cover the cost of the boiler chimney in connection with the steam-engine plant, then the buildings for the gas-engine plant would be considerably less than £2,000, as no chimney stack is required.—Yours, etc.,

CROSSLEY BROS., LIMITED.

Manchester, July 13, 1894. (D. H. Irwin, Director).

SIR,—I have been very much interested in noticing your article on "Gas *v.* Steam for Central Stations," but I do not consider that the comparison between the two is at all fair so far as the cost of fuel is concerned.

In the first place, there are very few parts of England where coal can be obtained at 6s. per ton, and there are very few parts of England also where anthracite coal cannot be obtained at considerably less than 24s. per ton, so that in both these cases the advantage would be considerably in favour of producer gas. In the neighbourhood of London, for instance, steam coal cannot be obtained under 14s. to 15s. per ton, and anthracite coal can be obtained at from 17s. to 18s. per ton. On the above calculation, instead of the balance being against producer gas, there would be a balance of about £100 in favour of it.

I also notice that you put down the cost of an overhead traveller for six tons at £200 in one case and £300 in another. I am erecting a six-ton overhead traveller at the present moment with 36ft. span for less than £100.—Yours, etc., HENRY ROGERS, M.I.M.E.

The Engineering Works, Watford, July 13.

REVIEWS.

The Electric Central Stations at Cologne and Amsterdam. By CARL COERPER. Translated from the German by CLARENCE P. FELDMANN. The International Electric Company, 55, Red Cross-street, Barbican, E.C.

We have received from the International Electric Company a copy of what they are pleased to term a ponderous work, but which we should be more inclined to call a magnificent work. It is perfectly certain that there is no other electrical work possessing, in a certain way, more value than this. A great many thoughtless people incline to the opinion that English people are great readers. No doubt that opinion is formed from the casual paragraphs which appear in ordinary newspapers to the effect that so many thousands or scores of thousands of readers have visited a free library, or that so many thousands of books have been lent therefrom. When, however, we come to analyse the reading of this reading fraternity, we find that it is mostly directed towards pleasure than profit. In other words, the majority of these readers are readers in name and not students. The class of reader which we should like to see extended is the student class. Unfortunately, this class is comparatively small in numbers, but in every department of life we find the men who make their mark are those who keep themselves well abreast with all that goes on in their respective industries. The electrical engineer cannot have had a long experience nor a varied one, so far as he is personally concerned, and he can only extend his experience by carefully considering

Digitized by Google

the experience of his colleagues, and he must learn both from their successes and their failures the steps which he ought to take in his own practice to lead him to succeed. Such a work, then, as we have named above ought to be of immense value, in that it not only describes two very fine central stations, but it also illustrates upon a very large scale, and in an excellent manner, the whole of the details of these stations. This will readily be seen when we give as the dimensions of many of the illustrations a size of 24in. by 18in. or 19in. There are 33 large engravings of this kind, in addition to some 60 smaller illustrations interspersed with the descriptive text.

We have at various times referred to these installations in our pages, but it is evident that our references have been too meagre, and that the work of these stations ought to be, even by English electrical engineers, more carefully examined. We hope to be permitted to do this from time to time. Take, for example, the tabular statement which takes the distribution of energy delivered to customers. This tells us not only that there are a certain number of customers at Cologne, but the class of customers, the energy delivered to the various classes, the number of lamps both of arc and incandescent, giving the equivalent of these lamps and 16 c.p. lamps—which, by the bye, we prefer to the English system stating equivalents in 8-c.p. lamps—concluding with a column showing the mean annual hours with mean annual number of lamps. We find in this last column that 122 is the smallest number of hours, and stands against private houses there; 585 is the largest number of hours standing against factories, workshops, and warehouses, thus leaving out the number of hours at the station itself, which is not usually a figure required in calculations. The next largest item is 550 hours for the restaurants, hotels, etc., banks and offices reading 420 hours, and shops 413 hours. The financial results of the working at Cologne are stated to be 141,354 marks, distributed as interest, redemption, and fund for renewals; while Amsterdam has earned 82,646 florins, half of which have been distributed as interest on the bonds.

These few remarks will suffice for the moment to call attention to this magnificent work, and we must leave for the future any other remarks we may feel inclined to make.

The author of this book is the managing director of the Helios Company, and he describes herein work that has been carried out under the company.

SOME STORAGE BATTERY PHENOMENA*.

BY W. W. GRISCOM.

(Concluded from page 48.)

This fall of temperature on discharge was first brought to my attention in 1887, when some of the cells of the Julien cars on Fourth-avenue, New York, were reported to heat unduly, and the explanation offered was that they were called on for increased currents on certain grades with unfavourable conditions of the tracks. As some of the cells did not heat, I was not satisfied with the explanation, especially as the resistance of the cells, about ·002 ohm, would only account for about 1¼ heat units even on 100 amperes discharge. I then investigated the question and found that the temperature actually fell even with heavy current, when the cells were in good order.

The potential of a cell is partly due to the degree of charge of the positive and partly to that of the negative and partly to the electrolyte. If a negative plate taken from a fully-charged cell indicating, say, 2·65 volts on the normal charging current, is coupled with a positive from a partly-discharged cell, indicating, say, 1·9 volts on its normal discharge current, the E.M.F. of the combination will lie between the two. If the couple be removed to a stronger or weaker electrolyte, the E.M.F. will rise or fall accordingly. So that a measurement of the potential difference at the terminals of the cell is not an infallible indication of its condition of charge. If both plates are equally charged the indication is most useful, but when, as frequently happens in actual service, one plate is further discharged than the other, the potential difference is deceptive.

The variations of specific gravity of the electrolyte are practically proportional to the ampere-hours of useful charge or discharge—barring local action, short-circuiting, change of temperature, and a gradual sulphating of discharged positives when idle.

The variations of the internal resistance of a cell afford a valuable indication of the condition of its active material, and therefore of its degree of charge. These variations have been attributed to the varying porosity of the active material—the electrolyte becoming more and more excluded as the pores become clogged. But this explanation does not account for the odd but invariable nature of the characteristic curves of the internal resistance. If this were the true explanation, why does the curve fall rapidly in the early part of the discharge instead of rising? Why should it remain constant for the greater part of the useful discharge? Why should it suddenly rise to a great degree, and then fall in the middle of a prolonged charge? Why is the internal resistance less instead of more on a higher rate of discharge? These facts are not easily reconcilable with the clogging theory, and our knowledge of the chemical reaction is not sufficient as yet to afford a convincing explanation.

Experience shows that it adds greatly to the life of a cell and brings other advantages to stop the charge at between 2·3 and 2·45 volts, and to stop the discharge at 1·90 or 1·95 volts, while a comparison of the accompanying curves of a cell will show that these potentials are reached shortly before or during a sudden rise of the internal resistance.

A very curious misapprehension prevails among some battery people, in spite of the airing the subject has again and again received, to the effect that the negative plate has more capacity than the positive. If a cell be discharged at a high rate—to 1·88 volts, for example—the positive plate will show a much lower potential than the negative, and might therefore be deemed to be more discharged. If, then, the negative element be transferred to a freshly-charged positive element, the negative will usually show a considerable additional capacity, and this has been cited as a proof of the erroneous statement. But if the positive be similarly treated, it usually shows considerably greater capacity than the negative. This is especially the case with the Faure cell, in which the positive actually has 25 per cent. more volume of active material than the negative, and shows 45 per cent. more capacity; and is even so on a Planté negative, which has as much active material as the positive, and yet the latter has nearly 10 per cent. more capacity.

The positive plate is usually made of greater capacity than the negative in order to prevent it from ever becoming discharged, to allow for its gradual loss of active material, but there are grounds for doubting the propriety of so doing. A negative plate ought never to be discharged so far as to drop after the first 10 minutes more than 1 or 2 per cent. in voltage, yet the temptation to do so with 45 per cent. excess of capacity in the positive is very great—with the result of causing shrinkage of the negative paste and a serious loss of capacity in the cell.

There is another action which goes on in storage batteries, and presumably in other forms of electrolyte chemistry, which I have not seen explained, nor, in fact, described. When the chemical reaction in an electrolytic cell are simple, as, for example, decomposing sulphate of copper or sulphate of zinc, the amount of action is proportional to the ampere-hours. But when the possible chemical reactions are complex, as in a storage battery, the changes are governed by the potential difference, as well as by the current, probably because one of the components requires a different E.M.F. to break it up from that required by another. A curious result ensues. Perhaps the current governs the amount of chemical action and the potential the kind. Our factory department reports that if a plate pasted with red oxide of lead is opposed to a plain lead grid in a "forming" bath, the formation of peroxide proceeds evenly and uniformly in the well-known way. If it be opposed to a pasted

* Paper read at the American Institute of Electrical Engineers,

Digitized by Google

negative, the same result follows. But if it be opposed by another positive plate a different action ensues, and the unformed plate cannot be properly converted to peroxide until the other positive has been completely reversed and converted into a negative, thus raising the potential difference of the cell. In the curve of the Faure cell it will be noted that at the time the potential of the piles suddenly rises, due to the sudden increase of the potential of the negative plate, there is at the same time a sudden increase of the internal resistance of that plate. This is, however, accompanied by a sudden and apparently sympathetic perturbation of the internal resistance of the positive plate, showing that some chemical change occurred in it, quite different from the usual action. This perturbation ceased as soon as the negative potential ceased to rise.

There are two other phenomena to which I will refer briefly in the hope that some members may be able to throw some light on their cause—viz., the sudden spontaneous discharge of a fully-charged positive, and the tendency to buckle away from the light—*i.e.*, with a concave face toward the light. Wherever the tendency to buckle is great, as in treating Planté plates in some of the more rapid methods, I have observed that when a single positive is suspended freely a great distance from a negative in the centre of a large jar, the buckling is invariably away from sunlight. The plate may be turned around, it may be moved quite close to one negative or the other, yet the buckling repeats itself invariably from the light. The plate may be straightened as you will, it may be left with a slight curve in the other direction, yet neither the natural differences of tension in the two sides of the plate nor the increase or diminution of electrolytic action on either side has any influence in buckling compared, apparently, with the action of direct sunlight.

It will be remembered that Prof. Ayrton, in one of his valuable contributions to storage battery literature, commented on the theory of Mr. Crompton regarding the effect of light on the sulphating of the negative plate, and detailed an interesting experiment which, although not conclusive, tended rather to confute this theory. Sir David Salomons remarked upon the effect of light on the glass cells causing them, he said, to crack. Altogether it would seem that storage batteries are devices which engineers would do well to keep in the dark.

The automatic discharge of the positive plate is a comparatively rare phenomenon. In my experience I have secured accurate data in only three instances. I am under the impression that Sir David Salomons, when by his courtesy I was enabled to examine his splendid private plant in 1886, mentioned this phenomenon, but I do not find it described in his book, and as it may not have recurred in his experience he may have felt some hesitancy in publishing it.

On one occasion a cell was reversed experimentally, and the reversing charge continued until 470 ampere-hours, or three times the normal capacity of the cell, had been passed through it. The potential attained 2·41 volts on a low charging rate. The positive had the healthy dark colour of electrolytic peroxide of lead and was freely gasing, showing that it was as fully charged as possible. The charging current was interrupted, and the E.M.F. fell gradually to 2·12 volts in a perfectly normal way. In 35 minutes a curious seething sound attracted my attention to the battery, and I found it in a state of violent, almost explosive, ebullition. The gas given off was pure oxygen in immense quantities. The temperature at the botttom of the cell had risen from 68deg. F. to 85deg. F., and at the top of the cell it reached 109deg. F. Fifteen minutes later the cell was quiescent, the voltage had fallen to ·84, and the specific gravity from 1·157 to 1·123—the lowest point which it had reached 470 ampere-hours before. Two or three days later the E.M.F. was zero.

During the progress of the phenomenon and afterward the cell was examined carefully with the most minute care for any defect, short-circuit, or other irregularity, and it was found to be in perfect order. A further charge of 876 ampere-hours, or about six times the normal capacity, was given at a normal rate. On this charge as well as on the first reversal charge another curious effect was observed—the voltage rose in 15 minutes from zero to 0·18; in one minute more it jumped to 2·63. It then gradually fell to 2·01 in about seven hours and thereafter gradually rose to 2·48. The discharge was normal to 148 ampere-hours and presented a peculiarity of a fully-charged cell—that is to say, the E.M.F. fell in two minutes from 2·05 on 30 amperes to 1·935, and then rose in a few minutes more to 1·94 volts, and then gradually fell the usual way.

Here, then, is the story of a complete automatic discharge of positive plates from the beginning of the preceding charge to the end of the following normal discharge. Was it because the peroxide formed only to a certain depth in a spongy lead and so densely as to exclude the electrolytes for a time, so that when the liquid at last penetrated the spongy lead a violent local action ensued? This would account for the heat, and for the fall of potential and of specific gravity, but would it account for the liberation of immense volumes of oxygen? I have frequently noticed the presence of considerable quantities of peroxide of hydrogen in electrolytes. Gladstone and Tribe have also remarked this substance, but intimate that they found it in minute quantities only. In some cases, however, I have observed it in very considerable amounts. Is it possible that this substance was present and exercised its well-known property of liberating one atom of oxygen from peroxide of lead and another atom of its own oxygen at the same time? This would account for all the phenomena, but what accounts for the peroxide of hydrogen in such an enormous amount, and why does it not always discharge oxygen from the peroxide? And finally, is it possible that the continuous evolution of oxygen on the positive plate while the cell is idle is sometimes due to the presence of peroxide of hydrogen in minute amounts, and not merely to what has been called local action? I trust some of the gentlemen present will enlighten us on this point.

Perhaps the most striking peculiarity about the modern storage battery is the diversity of opinion among professional electricians as to its utility and commercial value. Men of the highest rank as electricians and engineers are ranged on either side of the question. Men of affairs who have put them to a commercial test exhibit a like divergence of views. Men who have tried the storage battery for a year or two have written about it in the most flattering terms and have discarded it later. Men who have used accumulators ever since their introduction, when they were much less efficient machines than now, continue to use them, and would under no circumstances be induced to part with them. Unmitigated praise on the one hand and unmitigated contempt on the other. Broadly stated, the European consensus of opinion, both technical and commercial, may be said to be in favour of storage batteries. The American view until now has been mainly the opposite. What is the ground for this wide discrepancy? Why is cautious, conservative Europe so far ahead in the race? Why is America a laggard in the running?

The answer is not far to seek. Storage batteries are almost always an economical success abroad, while here they have been too often an economical failure in the past. And the reason is that the European always demands a margin for safety, while the American, with less capital and keener competition, is tempted to sail too close to the wind.

A storage battery continually worked to its commercial rating is a commercial failure. A storage battery worked sufficiently within its capacity is invariably a commercial success.

It has been said of Watt that he pursued careful and exhaustive experiments upon the power of horses for all day work, and that he ascertained that the average power which they could maintain for 10 hours was 22,000 foot-pounds per minute, but in rating his engine he added 50 per cent. and called the horse-power 33,000 foot-pounds per minute, so as to make his new pumping devices more than satisfactory substitutes for horses. Would that storage battery people had been equally wise.

The writer has had occasion to watch with the closest scrutiny a considerable number of plants, aggregating perhaps some millions of plates. These batteries were rated, like all reputable makes, well within their capacity

Digitized by Google

in ampere-hours measured by charging the battery to about to 2·65 volts, and then discharging it until the potential difference was 1·8 volts per cell. Some batteries have been spoiled by bad management and neglect, and some by false economy or bad engineering at the very start. By eliminating these there remain a very large number which were successful or were failures for no apparent reason. The utmost care was exercised at the factory. The constituent materials were analysed as soon as purchased. Able engineers watched the processes of manufacture, but while the quality of the battery was improved until no flaw, mechanical, electrical, or chemical seemed to remain, still an occasional failure occurred in actual practice, and the cause eluded our search.

Finally, by classifying the failures and successes, the truth dawned upon us. Wherever the battery was exhausted to its full capacity daily, its life did not exceed 500 discharges, but wherever it was worked within two-thirds of its capacity, complaints were unknown.

Exhaustive tests were undertaken, and some curious phenomena heretofore unknown to the writer were disclosed, and after some hesitation he concluded that they might be of interest to this society.

It is natural to ask why the rating should not be changed so that the owner of the battery would not be tempted to work it to the danger limit. That is a commercial question. In these days of close commercial figuring it would be difficult to sell a battery which appeared *cæt ris paribus*, to cost 50 per cent. more than its competitors. The present rating is strictly accurate and has the sanction of custom the world over. It is only necessary for the engineer to remember to add 50 per cent. of the capacity as a factor of safety to his maximum load, just as he allows several hundred per cent. in calculating the strength of a bridge or axle.

This additional amount is not a dead loss in investment. It produces many countervailing advantages. It saves the necessity for regulation in most instances. It provides a very effective and safe reserve for cases where the charging apparatus breaks down and for many other cases, and it improves the actual efficiency of the battery, which arises from about 80 per cent. to nearly 90 per cent. when used with a sufficient reserve. And for cases where it is necessary to maintain a constant difference of potential, such as electric lighting, it raises the efficiency much more, because in these cases the commercial efficiency must be rated not from the average point of E.M.F. but from the lowest point to which the battery falls on discharge, and when used in this way the potential difference drops only 2½ per cent. All the E.M.F. above the lowest point must be wasted in order to secure regulation, unless the troublesome method of regulating by the introduction of extra cells is adopted.

In circuits where this regulation is of no consequence, as in motor circuits for cars, all the E.M.F. is utilised in increasing the car miles per unit of energy.

In this connection it is perhaps worth while to call the attention to a very common misapprehension on the part of engineers. A storage battery for trolley systems or other central stations for the production and utilisation of electricity has heretofore been regarded in this country as a very expensive addition to the plant. But this is not always the case. There are many opportunities for introducing storage batteries as a part of the original plant without increasing the cases, as, for example, in cases where the maximum output is two or three times greater than the average output. In the tables here given I have taken Emery's figures for a basis for the steam plant.

1,000 h.p., Direct System.

Cost of steam plant	$70,000·00
Electric plant, 750 kilowatts, at 30dol. per kilowatt	22,500·00
	$92,500·00

1,000 h.p., Storage System.

One-half steam plant	$35,000·00
One-half electric plant—375 kilowatts	11,250·00
1,500 kilowatt-hours, accumulator capacity, at 30dol. per kilowatt-hour	45,000·00
	$91,250·00

Now that batteries are made in large units and in much more compact shape than formerly, with increased facilities for handling, it is to be hoped that the engineers in this country will begin to give the subject of their introduction more attention, especially as a cell having a capacity of 24 kilowatt-hours occupies a floor space (exclusive of connections) of less than a square yard.

A battery's discharge should be stopped after its E.M.F. has fallen to two volts, or at furthest to 1·9, unless it be desirable to draw upon its reserve. It should be understood that a full discharge—that is, to 1·8 volts—is working a battery to the danger limit, and is unadvisable for the following reasons: (*a*) regulation is troublesome; (*b*) efficiency is low; (*c*) dangerous molecular changes take place, as indicated by changes of internal resistance and changes of E.M.F., as well as occasional buckling; (*d*) uneven plates discharge into one another after the circuit is interrupted; (*e*) the life of the battery is diminished.

I desire to acknowledge the aid I have received in the study of these phenomena from my very competent laboratory assistants, as well as the accurate and fatiguing work, both night and day, kindly undertaken by two of them, Hugh Lesley, aided by Norman Mellor, in making the measurements and plotting the curves herewith presented for your consideration.

TRAMWAYS IN GERMANY: A COMPARISON BETWEEN THE COST OF HORSE TRACTION AND ELECTRIC TRACTION.

In the *Foreign Abstracts* of the Institution of Civil Engineers an article on the above subject is given from the *Zeitschrift für Transportwesen und Strassenbau.* It is as follows:

The comparison is founded on many years' experience of an important German tramway company in horse traction (the situation of which, however, is not given), and by carefully obtained trial results in electric traction.

The tramway selected is 8·08 miles in length, and establishes intercourse between a large town and several suburbs. The time-table is so prepared that the trams run at 6.0, 6.30, and 7.0 a.m., and then every quarter of an hour until 9.0 p.m., after which they run at 9.30, 10.0, 10.30, and 11 p.m. The car, which is a one-horse one, carries 30 persons inclusive of driver and guard; on 20 days of the year it is necessary to double this service.

With the use of horse traction, a speed of eight to ten miles an hour is the limit, and eight cars are required for the service; 126 (2 × 63) single tours are made daily, and 1,018·08 (126 × 8·08) car miles are run, consequently 391,961 [(365 + 20) × 1,018·08] car miles are run in the year.

As the daily performance of a horse in tramway work amounts on the average to 16 miles, theoretically 63 horses are required for the usual traffic, but in practice 10 per cent. more are added to make allowances for disease and rest, so that 70 horses are kept. The 70 horses represent a capital of £3,150 (70 × £45), and a further sum of £4,250 is required for land and buildings. The following tables are then given as representing the yearly cost of horse traction.

I. Payment of Interest and Depreciation.

4 per cent. interest on £7,400 (£3,150+£4,250)	£296	0	0
15 ,, depreciation of capital value of horses	472	10	0
1½ ,, ,, ,, ,, buildings	63	15	0
Total	£832	5	0

II. Cost of Management.

Salary of manager	£90	0	0
Wages of eight drivers	360	0	0
Wages of six stable-boys	150	0	0
Provender for 70 horses	2,175	0	0
Harness and shoeing	287	10	0
Veterinary treatment	65	0	0
Repair of stables, etc.	100	0	0
Sundries	72	12	0
Total	£3,300	0	0

These two sums, amounting to £4,132. 5s. yearly for 70 horses, gives 3s. 2·8d. per horse per day. But to this sum is still to be added the hiring price of 63 horses for

Digitized by Google

20 days at 5s. per day, which amounts to £315. Therefore the total yearly disbursement for horse traction is £4,447. 5s., the cost per car mile being 2·72d. $\left(\frac{£4,447.\ 5s.}{391,961}\right)$.

The estimate for electric traction is founded on the overhead line system of O. L. Kummer and Co., of Dresden. Each car is provided with two electromotors of 8 h.p. The capital required is estimated as follows:

Land	£150	0	0
Buildings	1,600	0	0
Boiler and engine and two dynamos, including all fittings	3,750	0	0
Length of 8·08 miles of line work, fixed complete	3,500	0	0
Electric fittings for nine cars, one of which stands in reserve	2,250	0	0
Total capital expenditure	£11,250	0	0

The following tables are then given as representing the yearly cost of electric traction:

I. Payment of Interest and Depreciation.

4 per cent.	interest on £11,250		£450	0	0
1½ ,,	depreciation on buildings account		24	0	0
7½ ,,	,,	engine, etc., account	281	5	0
5 ,,	,,	line work account	175	0	0
15 ,,	,,	electromotors account	337	10	0
Total			£1,267	15	0

II. Cost of Management.

Salary of manager	£90	0	0
Wages for three enginemen	180	0	0
Fuel	830	0	0
Carriage of cinders	10	0	0
Lubricants	125	0	0
General repairs	225	0	0
Sundries	72	5	0
Total	£1,532	5	0

These two sums, amounting to £2,800, give 1·72d. per car mile as the cost of electric traction.

The paper concludes in enumerating several advantages that electrical cars possess over the horse cars in the matter of speed, safety, and size in crowded streets, as well as in cost.

THE LONDON COUNTY COUNCIL AND METROPOLITAN SUBWAYS.

PROPOSED REGULATIONS.

The Highways Committee of the London County Council reported to that body on Tuesday that by Section 10 of the London County Council (Subways) Act, 1893, the Council is empowered to make, vary, and enforce by-laws regulating the use of all the subways vested in it at the time of the passing of the Act, and by such by-laws to fix and determine the scale of fees to be paid for the use of the subways, and the penalties for breaches of the by laws. The by-laws when made by the Council are, however, not to come into effect until they shall have been confirmed by the Board of Trade. Notice of the intention to apply for such confirmation is to be given to the Postmaster-General; and such other notices as the Board of Trade may prescribe are also to be given before the Board takes the by-laws into consideration. The committee have given consideration to the question of what restrictions and conditions should be imposed upon companies and others using the Council's subways, and have prepared a draft code of by-laws which in their opinion should be made by the Council.

These by-laws do not apply to any pipe or wire authorised to be laid or placed by any provisional order or license under the Electric Lighting Acts, 1882 and 1888, or under any special Act incorporating the said Acts or (in respect of such wires) to any company authorised to lay or place the same.

The following are the by-laws which the Council is asked to make:

1. Fourteen days at the least before the day on which any company, body, or person desires to place or bring any pipe or wire into a subway, such company, body, or person shall give notice in writing to the Council of such desire accompanied by full particulars in writing of the position and manner in which such pipe or wire is proposed to be brought into and placed in the subway; the dimensions and full particulars of any pipe or wire that is proposed to be placed or brought into the subway; and also the proposed method of supporting the same, and, in the case of a wire, particulars of the insulation and highest E M.F. for which it will be used. No company, body, or person shall place or bring any pipe or wire into a subway until the Council shall have signified its consent in writing under the hand of its engineer to the position and manner in which such pipe or wire is to be placed, and to the method by which such pipe or wire is to be brought into the subway.

2. Fourteen days at least before the day on which any company, body, or person desires to take any pipe or wire out of a subway such company, body, or person shall give notice in writing to the Council of the manner in which such pipe or wire is proposed to be taken out of the subway. No company, body, or person shall take any pipe or wire out of the subway until the Council shall have signified its consent in writing under the hand of its engineer to the manner in which such pipe or wire is to be taken out of the subway.

3. A company, body, or person desiring to repair or alter any pipe or wire in a subway shall (except in case of emergency) give three days' notice in writing to the Council of the manner in which such repair or alteration is proposed to be made, and shall not commence such repair or alteration until after obtaining the consent in writing of the Council to the same under the hand of its engineer. Should any case of emergency arise, particulars in writing of any work done shall be forthwith sent to the Council's engineer.

4. No company, body, or person shall commence the execution of any work which will involve the alteration and reconstruction of any part of a subway until the expiration of 48 hours after such company, body, or person shall have given to the owner of every pipe or wire in the subway notice in writing specifying the nature of the work and the time at which it is to be commenced.

5. No company, body, or person shall take into a subway any candle, lamp, or light other than a safety lamp of a pattern approved by the Council, or smoke, or take, strike, or use therein any match, without the consent in writing of the Council under the hand of its engineer.

6. No company, body, or person shall open or raise any grating or other means of access to a subway or enter therein (except in case of emergency) without the consent in writing of the Council under the hand of its engineer. N.B.—The keys of the subway entrances will be kept at such places, and by such officials, as may from time to time be appointed by the Council for the purpose; each company, body, or person having pipes in a subway will be supplied by the Council with a card stating the places at which and the names of the officials in whose custody the keys are kept, which card shall be produced to the official whenever application is made for access to a subway; and such officials will arrange for the opening and closing when required of the gratings or covers for persons entering or leaving a subway.

7. No company, body, or person shall allow any grating or other means of access to a subway to be opened or to remain open without providing a temporary fence or protection and leaving a watchman to guard the same.

8. No company, body, or person shall (except in case of emergency) enter or remain in a subway between the hours of 6 p.m. and 6 a.m.

9. Every company, body, or person having a pipe or wire in a subway shall within six months of the confirmation of these by-laws deposit with the Council full particulars in writing of such pipe or wire, stating name of subway; date when first placed; position, dimensions, gauge, material, and purpose for which it is used or proposed to be used; nature of supports (if any); and within a further period of six months, if so required by the engineer of the Council, shall deposit with the Council a plan, on a scale of not less than 88ft. to 1in., showing the position, with such detail drawings as the Council may require.

10. Every company, body, or person depositing the particulars and plan required by the last preceding by-law shall, once in every subsequent year, cause such particulars and plan to be duly corrected to date.

11. No company, body, or person shall store materials in a subway, or allow any rubbish to accumulate or remain therein.

12. No person shall commit any nuisance in a subway.

13. All persons working or being in a subway shall conform to all reasonable instructions of the Council's officers.

14 Every company, body, or person using a subway shall pay to the Council on the usual quarter days in each year fees and charges according to the following scale: (*a*) a charge of 5s. for each day or part of a day during which a pipe or wire is being laid in or removed from a subway; (*b*) a charge of 1s. for opening or closing a subway at any time other than that fixed for the daily visit of the Council's officers; (*c*) an annual charge for use and supervision.

15. Any company, body, or person failing to comply with, or doing anything prohibited by, any of these by-laws, or any of the provisions of the London County Council (Subways) Act, 1893, or delivering to the Council any particulars or plans or making any connections therein which to their or his knowledge are incorrect, shall be guilty of an offence against these by-laws, and shall be liable to a penalty not exceeding £5, and to a further penalty not exceeding 40s. for each day during which such offence is continued after written notice of the offence shall have been given.

The names of the subways referred to are as follows: Garrick-street, Commercial-road East, Northumberland-avenue, Shaftesbury-avenue, Charing Cross road, Southwark-street, Queen Victoria-street, and Victoria-embankment.

The Highways Committee recommended that the Council make by-laws in the above form; that a copy of the by-laws be sent to the Postmaster-General, with a notice of the Council's intention to apply to the Board of Trade for confirmation of them; and that the clerk be instructed to make the application to the Board of Trade, and to do all things necessary to give effect to any order which may be made under the Act by the Board, prescribing what notices shall be given of the intended by-laws previously to their being considered by the Board.

THE CITY COMMISSION OF SEWERS AND TELEPHONE TUBES.

THE CITY ELECTRIC LIGHTING COMPANY'S DILEMMA.

Some lively proceedings took place on Tuesday at a meeting of the Commission of Sewers in connection with the telephone tubes put down by the City of London Electric Lighting Company.

Mr. Gordon moved the following resolution, which was referred to in our issue of the 6th inst.: "That the resolution of this Court of July 25, 1893, agreeing to a recommendation of the Streets Committee, that the Commissioners only consent to the use for telephonic purposes of certain tubes laid by the City of London Electric Lighting Company, on a guarantee being given that telephones with double wires and all the latest improvements will be supplied to the citizens at a cost not exceeding £8 per annum be rescinded, and that an offer of the said company to pay the Commissioners '10 per cent. of any annual rental, so long as such may be received for the use of any tubes for telephonic purposes, up to the sum of £10,000 per annum, and 20 per cent. on any rental in excess of £10,000' be accepted, provided the minimum amount to be received by the Commissioners be £1,000 per annum, subject to a proper agreement being entered into with the company, without prejudice in any way to the rights and privileges of the Commissioners under the contracts and provisional orders." Mr. Gordon said he wished to test the feeling of the Court, as the members of the Streets Committee were pretty evenly divided. There was no doubt in his own mind that the tubes were laid down without applying for permission in a proper manner. They were laid down surreptitiously, and the company should be punished according. In order to carry out that intention the Court adopted a resolution on July 25 last asking the company to reduce the cost of telephony. But he had since realised that the Court had no *locus standi* to do that. There was no doubt that the Court was wrong as the proposed concession affected only 3,000 subscribers or users of telephones, which were a luxury. But by the second part of his motion, on a sliding scale the whole community would be affected. And it was much better as a matter of principle that that should be so. If the Court persisted in its present action it would stultify itself. A contract had been entered into by the electric lighting company and the telephone company, whereby the latter agreed to pay the former 10 per cent. on the cost of the tubes, the cost being estimated at £100,000 That represented a minimum rent of £1,000 a year. The assessment of them would not be less than £2,500, making £3,500 per annum, which could be used in relieving the rates. He had reason to believe that within two years the rent would be increased to double, or about £20,000 a year. According to that offer, the Court could claim 20 per cent. on the second £10,000. In all, the sum of £8,000 would be available for reducing the rates.

Mr. Sayer, in seconding the resolution, said he wished to disagree with Mr. Gordon in his assertion that the electric lighting company had laid the tubes in a surreptitious manner. It was true the committee had never given its consent, but he had thought all along that the laying of the telephone tubes in the same trenches with the electric lighting tubes would be for the benefit of those carrying on business in the City. The tubes were accordingly laid and the company received the consent of the Court afterwards, and he certainly thought the Commission would receive some concession from the company in consequence Those tubes were now rotting, and under the present state of things the Commission was losing a large income. He hoped, therefore, that no further delay in securing that would be permitted.

Mr. Morton challenged the remarks made by Mr. Sayer to the effect that the tubes in question had been laid down by the consent of the Commission, and the whole thing, he said, originated in the imagination of Mr. Sayer. It was of no good for members to come to the Court with such cock-and bull stories, for it was well known that the Commission refused to give its consent to the laying of the tubes. The silence of the Court on the question could only mean that its consent was withheld. The fact was, Mr. Morton said, the directors and chairman of the company had been about the members of the Court, but he did not know how it was the latter had changed their minds. It had not affected his mind, for he remained of the same opinion. The committee had, moreover, no right to negotiate with the company, and in doing so it had gone out of its way.

Mr. Pannell had never heard a more astounding argument than that advanced by the last speaker. The proposition before the Court was that all classes of the citizens should share in any advantages that were likely to accrue under the proposed arrangement, and he was all the more surprised to find Mr Morton, who ably represented the majority and the masses, refusing to consent to the rescinding of the former resolution, by which only a comparatively few persons would benefit. He (Mr. Morton) insisted that the benefit should be shared only by the users of telephones, which were used by those persons for their own business purposes. As to the statement that the Court did not know the tubes would be laid, he contended that the Commission was from time to time kept thoroughly acquainted with the various applications that were made by the company for the laying of the tubes. The assertion that they were laid by means of a subterfuge and in concealment was therefore entirely erroneous. He appealed to the members to adopt the present resolution as one which would benefit, not a section of the citizens, but the community as a whole.

Mr. Deputy Scott observed that he was the chairman of the Commission at the time the question of the tubes was before the Court. He had no hesitation in saying that the various sections were shown, and it was stated at the time that the tubes which were to be placed therein were for telephonic purposes. It was also a matter of fact that the company might have gone to Parliament had it chosen for powers to reopen the streets again for the purpose of laying them—an eventuality, he submitted, which would have been intolerable to the citizens. The tubes were down, and, in his opinion, the Commission had no right to act like dogs in the manger and prevent the use of them, or the citizens gaining any benefit from their use.

Mr. Barham hoped the Court would not rescind the resolution it adopted 12 months ago. The electric lighting company had stolen a march upon the Commission, and, so far as he was able, he would never permit it to reap the advantage; but, on the contrary, would do all he could to force it to make concessions to the citizens. The people of London were, he said, as much entitled to secure cheap telephones as those living in Liverpool or Manchester, and yet it was proposed that the Commission should sell its birthright for a mess of pottage.

Mr. Deputy Bowring trusted that the Court would think twice before rescinding the resolution it had adopted.

Mr. Bridgman expressed his surprise at hearing assertions made to the effect that the citizens had been sold. In 1892, he said, applications were made by the company for permission to lay the tubes, and, after receiving a report from the engineer, the Streets Committee resolved on April 13, 1892, that no action should be taken. If anyone could stand up, therefore, and say the Court had been sold, then it was simply a reflection on the business acumen of the person who was prepared to say so. But the decision he had spoken of was not reported to the Court, and that was the fault of the Streets Committee.

Mr. Wallace appealed to the Court to affirm the principle advocated by Mr. Gordon.

Mr. Burmester wished to repudiate in the strongest possible way the unworthy suggestion Mr. Morton had made as to why certain commissioners should change their minds. He was willing to admit that the Court misunderstood the real drift of the question when the other resolution was agreed to, but really the laying of the tubes had nothing to do with the question. The present proposition was in the nature of a fine, which would hit the electric lighting company rather hard, and it showed that the Court was ready to punish. He considered that in the name of the ratepayers the Commission had no right to throw away an offer which would afford considerable benefit to the community at large.

Other speakers followed, and after **Mr. Gordon** had briefly replied to the debate the motion was put in two sections.

On a show of hands 22 voted for the first section and 18 against it A division was claimed, with the result that 25 voted for and 19 against. As a two-thirds majority was necessary, the section was declared to be lost. The matter then dropped.

COMPANIES' MEETINGS.

WEST AFRICAN TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting was held last week at Winchester House. Sir John Pender, M.P., presided.

On moving the adoption of the report, he stated that the gross revenue for the year had been £61,847, or £924 in excess of that of 1892 There had been an increase in Cape joint-purse traffic and in certain local traffic, but in the traffic with the French and British stations and with South America there had been a decrease, so that the net increase in message receipts was £644. Although the loss on exchange was still very heavy—namely, £7,751—it was £293 less than it was in 1892. The cost of repairs last year had been exceptionally heavy, but in view of their relations with the other companies, who were so much interested with them in the joint-purse traffic with the Cape, it was absolutely necessary that every endeavour should be made by them to maintain the through communication. They had, therefore, at considerable cost diverted the cable, as far as it was considered necessary, out of the region affected by the River Congo, and they could only hope that the cable would now be free from the frequent interruptions which had occurred in that district. In order to meet the deficit and to balance the revenue account they had applied £10,741 from the reserve fund, and they trusted that the result of next year's working would prove more satisfactory.

Sir Henry C. Mance seconded the motion, which was adopted.

ELECTRICAL POWER STORAGE COMPANY, LIMITED.

Directors: John Irving Courtenay, Esq., chairman and managing director; Sir Daniel Cooper, Bart., G.C.M.G; Frederick Green, Esq.; James Pender, Esq. Manager: Frank King, Esq., M.I E.E. Secretary: J. W. Barnard.

Report of the directors presented to the shareholders at the fifth ordinary general meeting held on Thursday, July 19, 1894, at the offices of the Company, 4, Great Winchester-street, E.C.

The net profit for the year is £4,936. 4s. 11d., which, with a balance of £158. 19s. 5d. from last year's accounts, amounts to £5,095. 4s. 4d., out of which the directors recommend the payment of a dividend of 5 per cent. on the ordinary share capital, which will absorb £4,101. 10s. 2d., leaving £993. 14s. 2d. to be carried forward. Provision has been made for the effective main-

Digitized by Google

tenance of buildings, plant, tools, etc., at a cost of £2,297. 6s. 2d. The sum of £3,323. 1s. 4d., the proceeds of sale of the Company's shares in the Société Française, together with a further sum of £4,000 out of the profit of the year's working, and £1,500 written off patents in 1892-3, have been applied to the formation of a reserve fund for diminution in value of assets, as shown in the balance-sheet. The directors are pleased to be able to report the continued success of the Company's operations, and that there has been during the year a substantial increase of orders and of the uses to which batteries are being applied. The reduction in the selling price of the Company's manufactures has operated towards increasing the number of users, and so extending the goodwill of the business. Constant attention has been devoted to improving the conditions under which E.P.S. batteries are manufactured, and the directors are sanguine of further success in this direction. The development of electric traction has received the unremitting attention of the manager. The Company and its licensees have been successful in patent litigation abroad. The retiring director is Mr. Frederick Green, who, being eligible, offers himself for re-election. The auditors, Messrs. James Meston and Co., chartered accountants, also offer themselves for re-election.

BALANCE-SHEET, MAY 31, 1894.

Dr. Liabilities.	£	s.	d.
Share capital authorised—20,100 shares of £5 each, of which 100 are founders' shares	100,500	0	0

Mr. John Irving Courtenay, who occupied the chair, said that he proposed to offer but few observations, as the directors' report and statement of accounts spoke for themselves. They recommended a dividend of 5 per cent, and to carry forward a substantial balance to next year. The reserve fund stood at £9,315. 7s. 1d., and it was satisfactory that they had been able to bring it up to that amount. He was glad to be in a position to state that the volume of business had very considerably increased, and that the actual cash turn-over was larger than it was last year, although the reduction in the list prices of 20 per cent. had been in operation during the whole of the year under review. In this business there was an increasing competition, but the E.P.S. batteries had held their own thoroughly well. The policy adopted by the directors and manager had been to continually improve the quality of the Company's manufactures, and the results showed the E.P.S. batteries to be the most appreciated and reliable in the market; and that the sound commercial policy was to improve them in various details (though no startling new departure had been made), rather than to spend money and time in spasmodic efforts to obtain entirely new types or designs. One of the most important features to be noted was that the life of E.P.S. secondary batteries was steadily lengthening, so that, in fact, a sum equal to 5 per cent. per annum on the cost price was now amply sufficient for the maintenance in perfect working order of the batteries used under ordinary conditions. Those who remembered the pessimistic views expressed only a few years ago as to what would be the safe annual percentage to cover maintenance, would feel gratified at the practical illustration given by this Company of the correctness of the views of its representatives. The Chairman remembered being told that it would never pay any company to guarantee the maintenance of storage batteries at twice the figure now commonly adopted, but their manager had always contended that it could safely be done at about the present prices. Numerous fresh uses continued to be found for the employment of secondary batteries, and the number of their customers is larger than ever. They were not as yet able to point to a decided success in the application of E.P.S. batteries to traction, but they must make a success of this important branch of the industry, and the speaker believed that Mr. King would not fail in his efforts to this end, though the difficulties in the way of its development had been great. As stated in the report, unremitting attention had been given to the improvement of the batteries for traction purposes and to appliances in connection therewith, and he hoped that vehicles belonging to their friends the Pioneer Electric Carriage Company, Limited, fitted with the latest type of traction battery, would ere long be publicly working. During the year various improvements had been made in the plant and in the arrangement of the works at Millwall with the object of cheapening production but he did not consider it advisable to indicate more fully the direction these improvements had taken. Their works had been to a certain extent remodelled, and several suggestions made by the Board of Trade for the greater comfort and health of their workmen had been carried out. The Company's continental patents had been admirably protected by the Hagen Company and their legal and technical advisers, who had been most successful in upholding the patent rights. Mr. Courtenay concluded by moving the adoption of the report and accounts, and **Sir Daniel Cooper** seconded the motion, which was carried.

On the motion of **Mr. Courtenay**, seconded by **Mr. J. W. Barclay**, Mr. Frederick Green was re-elected a director.

On the motion of **Mr. J. W. Barclay**, seconded by **Mr. F. King**, Messrs. James Meston and Co. were reappointed auditors.

FASTERN TELEGRAPH COMPANY, LIMITED.

The half-yearly ordinary general meeting was held last week at Winchester House, Sir John Pender, M.P., in the chair.

The **Chairman**, after referring in detail to the chief items in the accounts, spoke of the money which their ships were earning, which was, he said, a new feature in their system of working; and the directors thought it a good plan, when their ships were not in service for themselves, to employ them in serving others who paid. The ships were kept well fitted for any emergency which might arise. He thought, upon the whole, that the report was favourable, and that they would all concur in that opinion. Paying the dividends they did, and carrying to the general reserve fund £110,000, was no small mark of success. This had been done during very bad times. He had been engaged in commercial life many years, and had never before known such a prolonged term of depression such as had existed, and still continued to exist, not only in London, but throughout the world. But there would be an end of this, and there was a boom coming, which was shown already in their colonies, and their energies would not long lie quiet. When the revival came there would be a great response from London, because, after all, a great amount of money had to come from London, and these times would be very good times for their submarine telegraph system. He moved the adoption of the report and the statement of accounts and the declaration of the dividends.

The **Marquis of Tweeddale** seconded the motion, which was carried.

CONTRACTS FOR ELECTRICAL PLANT.

CONTRACTS OPEN.

York Town (Surrey).—The Lighting Inspectors require by the 31st inst. tenders for lighting the street lamps for ensuing season—namely, September 1, 1894, to May 14, 1895. Specifications may be obtained of Mr. George W. Mason, secretary, York Town.

Warrington.—The Sanitary Works Committee of the Warrington Corporation require by the 23rd inst. tenders for the supply of a water-tube boiler. Specifications may be seen and further information obtained from Mr. James Deas, Longford Depôt, Warrington.

Bilston.—The Bilston Township Commissioners invite tenders by the 26th inst. for the electric lighting of their Market House. Specification of the works required may be seen on application to the clerk or to Mr. Wilson, C.E., township surveyor, at the offices, Town Hall, Bilston.

London.—The London County Council also invite by the 31st inst. tenders for the supply of boilers and fittings, steam and exhaust piping, surface condensers, and air-pumps for the station to be erected for the electric lighting of the embankment. Tenders are to be addressed to the clerk of the County Council.

Watlington (Oxon.).—The Lighting Inspectors invite tenders for lighting streets, roads, and other places comprised in the parish either with oil or with gas, or any other illuminant. Tenders should be sent at once to the Inspectors, Market-place, Watlington, of whom full particulars may be obtained.

Cheltenham.—The Corporation invite tenders by the 24th inst. for the supply of six 12-kilowatt transformers and 10 6-kilowatt transformers. Specifications may be obtained on application to the borough engineer, Municipal Offices, Cheltenham. Tenders are to be addressed to the Electric Lighting Committee, and are to be delivered to Mr. E. T. Brydges, the town clerk.

Rugeley (Staffs.).—The Local Board desire by August 1 tenders for the lighting of the street lamps for the winter season, commencing September 1, 1894, and ending April 30, 1895. Particulars may be obtained of the chairman of the Lighting Committee, Local Board, Rugeley, to whom tenders should be sent. The clerk to the Board is Mr. Robert Landor.

Nelson.—Those who are desirous of tendering for the wiring and fittings in connection with the new technical school may obtain plans and particulars (on payment of £1. 1s., which will be returned on receipt of a *bonâ fide* tender) by applying to Messrs. Holtom and Fox, architects, Dewsbury. Tenders are to be sent to Mr. R. M. Prescott, town clerk, Town Hall, Nelson, by 30th inst.

London.—The London County Council invite by Tuesday, the 31st inst., tenders for the supply of engines, dynamos, motors, switchboards, and other electrical appliances required for the electric light installation for the Victoria-embankment and Waterloo and Westminster Bridges. The drawings may be inspected and specification, bills of quantities, form of tender, and other particulars obtained at the Engineer's Department, County Hall, Spring-gardens, S.W., on payment of £2. This amount will be returned to the tenderer provided he shall have sent in a *bonâ fide* tender and not have withdrawn the same. Tenders are to be delivered at the County Hall in a sealed cover, addressed to the clerk of the London County Council, Spring-gardens, S.W., and marked "Tender for Engines, Dynamos, etc., for Electric Lighting Generating Station."

Edinburgh.—The Corporation of Edinburgh invite tenders for the following work in connection with the electric lighting of the city: Contract No. 13, supply and erection of Willans engines, alternators, etc.; No. 14, switchboard, instruments, and connectors; No. 15, arc lamps; No. 16, Ferranti rectifiers for arc lighting; No. 17, insulated concentric cable. Copies of the specifications can be obtained on application from the resident electrical engineer, City Chambers, Edinburgh. All information will be supplied by Prof. Alexr. B. W. Kennedy, the consulting electrical engineer to the Corporation, at his office, 14, Old Queen-street, Westminster, London, S.W. Tenders must be received in Edinburgh not later than 30th inst. for contract No. 15 (arc lamps), or on August 6 for contracts Nos. 13, 14, 16, and 17. Further particulars are given in our advertisement columns.

Harlow.—The Lighting Inspectors invite by August 4 the following tenders—(1) a tender for lighting the district from September 1, 1894, to April 20, 1895, from dusk until 11 p.m., excepting six nights before the two nights after full moon; (2) for cleaning, repairing, and painting one coat (in the colour now painted) of all the glass lanterns (inside and out), and refixing the lanterns in the columns and brackets, leaving all perfect and clean, ready for lighting on September 1, removing and storing at the end of the season the lanterns (including rent of storage), for keeping the whole of the lanterns during the season in good repair, and glazing when necessary; (3) for supplying new tinned copper-framed 14in. lanterns, glazed and painted similar to present ones, at per lantern. Further particulars may be obtained of Mr. W. E. Deards, secretary, Broadway, Harlow, to whom tenders are to be sent.

RESULTS OF TENDERS.

Wolverhampton.—The tender of Messrs. H. Willcock and Co. has been accepted by the Town Council for £372 for work at the electric lighting sub-stations.

Leith.—The Dock Commission have accepted the estimate of the Brush Company for the electric light installation at £3,300, and also the estimate of Messrs. R. Bruce and Sons to erect the engine-house for £640.

Bolton.—The Gas, Lighting, and Electricity Committee of the Bolton Corporation have accepted the tender of Messrs. Siemens Bros. for laying the requisite mains for extensions in Knowsley-street, as suggested by the engineer.

Worcester.—The Town Council have accepted the tender of the New British Electric Installation Contractors, Limited, for wiring and fitting up the Guildhall and police station. The Council have also accepted the tender of the same company for wiring the public hall, small hall, etc., at £177. 19s. 2d., and the tender of Messrs. Verity and Sons for the fittings at £154. 1s. 4d.

Tunbridge Wells.—The Town Council have accepted the following tenders:

Babcock and Wilcox, boilers	£1,726	0	0
Johnson and Phillips, engines and dynamos	2,778	13	0
Johnson and Phillips, arc lamps and posts	989	1	6
Johnson and Phillips, steam-pipes	277	10	0
Crompton and Co., transformers	832	14	0
Crompton and Co., switchboard	428	10	0
Crompton and Co., wiring of station	46	0	0
Callender's Bitumen Company, mains	2,306	12	0

BUSINESS NOTES.

Carlow.—Several additional lamps are to be erected by the Town Commissioners.

Aberystwyth.—The work in connection with the electric lighting of the town is progressing.

Western and Brazilian Telegraph Company.—The receipts for the week ended July 13 were £2,295.

Aberdare.—A new dynamo for lighting the Empire Music Hall has been put down by Messrs. George Wilson and Co.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 15th inst. amounted to £965.

Ipswich.—The Electric Lighting Committee of the Town Council are enquiring into a question of dust destructor.

Paddington.—The Vestry have resolved to enquire of electric lighting companies if they can supply electric light for the streets, and at what cost.

Central London Railway.—It is now said that the prospectus of the Central London (Electric) Railway will not be issued for some weeks to come.

Radcliffe.—The Electric Lighting Committee of the Corporation have nominated Mr. Hammond to advise them on electric lighting, at a fee of 50 guineas.

West India and Panama Telegraph Company.—The receipts for the two weeks ended July 15 were £114 more than for the corresponding period of last year.

Bristol University College.—Our advertisement columns contain a statement referring to the 1894-95 session (electrical engineering) of this university college.

Anglo-American Telegraph Company.—After placing £12,000 to the credit of the renewal fund, the directors announce a quarterly interim dividend of 10s. per cent.

St. Bride's Institute, E.C.—Messrs. Edmundsons, Limited, are carrying out the wiring of this institute according to the specification of Mr. W. H. Trentham, of Westminster.

Dewsbury.—Dr. Beattie has decided to have his house in Springfield-terrace lighted by incandescent lamps. The work will be carried out by Mr. A. R. Turner, of Dewsbury.

Whitechapel.—The report of the electrical engineer on the subject of introducing the electric light is to be considered at the next meeting of the committee of the Board of Guardians.

Hanley.—A letter has been received by the Town Council from the Local Government Board sanctioning a loan of £4,000 for the electric wiring and fitting of the various municipal buildings.

St. James's and Pall Mall Company.—The current sold by the Company during the quarter ending June 24 amounted to £7,380, as compared with £5,848 for the corresponding quarter of 1893.

Hampstead.—The Vestry have decided to make certain reductions, in the form of a sliding scale, in the charges for electrical energy where the annual invoice of consumers exceeds from £25 to £500.

City of London Electric Lighting Company.—The warrants for the interim dividend due on this Company's preference shares at the rate of 6 per cent per annum for the six months ended June 30 last have been posted.

Lambeth.—The Vestry has received notice from the St. James's and Pall Mall Electric Lighting Company that it intends to apply for a provisional order to supply electric light for private or public purposes in the district.

Arbroath.—The Town Council, having received an intimation of the intention of the Northern Electric Supply Company to apply for a provisional order, have decided to themselves apply for electric lighting powers.

Baslow and Burnell.—The Local Board have received an offer of a loan of money at 3½ per cent. to carry out an electric lighting scheme. The Board have decided to postpone the matter until the new council is formed.

Business Disposal.—An electrical engineer advertises that he desires to dispose of his business, established 15 years in London.

Digitized by Google

Communications are to be sent to Messrs. Cobbett and Co., 96, Great Russell-street, W.C.

Tunbridge Wells.—The Town Council intend to introduce the alternating system for public and private illumination, and to employ a Ferranti rectifier and transformer at the central station for dealing with the public lighting.

Denbigh.—The gasworks company having refused an offer of 3s. 8d. per 1,000 for the gas for the public lamps, the Town Council have agreed to consider the best steps to be taken to secure electric lighting for the town.

Rugby.—The Rugby School Electric Lighting Company are laying a new cable across the Hillmorton-road to supply the new science department, lecture-rooms, etc., which are being built in the schoolhouse gardens, with electricity.

Maidstone.—At a meeting of the Local Board a member enquired what had become of the electric light. Mr. Monckton, the assistant clerk, said he had received a letter from the company, and that the committee would meet at once.

Tuam.—The Irish Electrical Supply Company have notified the Tuam Town Commissioners that they intend to apply for a provisional order in the forthcoming session for the supply of electricity in the borough and district of Tuam.

Laying of New Mains.—The District Palace Electric Supply, the City of London Electric Lighting, and the House-to-House Companies have notified the London County Council of intention to lay down new mains in various thoroughfares.

Ramsgate.—The town clerk has been instructed to give the usual notice of opposition to a notice from the Brush Company, stating that the company intended applying for a provisional order to introduce the electric light in Ramsgate.

Nelson.—In a report on refuse destructors, a sub-committee of the Corporation of Nelson propose that a refuse destructor station should be erected at a cost of some £5,000, and that a dynamo for lighting the station by electricity should be laid down.

Hammersmith.—The Vestry have asked the Board of Trade to extend by two years the time within which to comply with the provisional order. The Electric Lighting Committee are examining the report presented to them by Messrs. Morgan, Williams, and King.

Postal and Packing Boxes.—Messrs. H. Nixdorff and Co., of 30, Maidstone-street, Hackney-road, N.E., have forwarded us samples of their wooden postal boxes for the transport of small electrical appliances through the post. The company also make packing boxes for larger goods.

Luton.—The Town Council have received a letter from the Municipal and Electric Lighting Corporation, Limited intimating that they would apply to the Board of Trade for a provisional order for the supply of electric light in the borough. The Council will oppose the application.

Plymouth.—Messrs. Hele and Co., of Wyndham-street, are now showing two fine organs at their manufactory. One is fitted with the Hope-Jones electric action, and is pronounced by the representative of the Hope-Jones Company to be superior to most organs of this kind of electric action.

Economic Electric Speciality Company, Limited.—This Company has been registered, with a capital of £50,000 in £1 shares, to carry on the manufacture and sale of electrical and scientific machines and instruments, and the business of mechanical, metallurgical, chemical, and general engineers.

Chiswick.—The Committee of Works of the Local Board have given instructions to the surveyor to press Messrs. Bourne and Grant to proceed with the plans and elevations of the building proposed to be erected at the pumping station for the purpose of providing the district with the electric light.

Fareham.—A number of ratepayers has signed a petition to the Board of Trade to withhold consent to the proposed purchase by the Local Board of the electric light company's undertaking until the new district council is in office, and until the company's undertaking has been valued by a competent authority.

Salford.—The annual report of the electric light department of the Town Council shows that the Corporation have raised £32,000 on loan. Of this sum they have spent on land, £2,972; on the generating and distributing station, £71; on mains and services, £54; and on preliminary matters, £376—leaving a balance of £28,527 unexpended.

Tonbridge.—The Holloway Electricity Supply Company have written to the Local Board that they intend to make application to the Board of Trade for a provisional order authorising them to supply electricity within the district of the urban sanitary authority of Tonbridge. The letter has been referred to the Highway and Lighting Committee.

Llandudno.—The Improvements Commissioners have received a letter from the Llandudno Lighting Company intimating that they intended to apply for a provisional order authorising them to supply electricity for public or private purposes within the area of the Commissioners. It was decided to refer the communication to the Water and Gas Committee.

Huddersfield.—The Town Council, on Wednesday, on the recommendation of the Electric Lighting Committee, appointed Mr. A. B. Mountain, who has superintended the construction of the electric lighting works, permanently as borough electrical engineer and manager, at a salary of £250 a year, this being an increase of £50 upon his previous salary.

Venezuela Telephone and Electrical Appliances Company.—Coupon No. 8 of the 5 per cent. first mortgage debentures of the Venezuela Telephone and Electrical Appliances Company, Limited, due July 31, will be paid from that date at the Consolidated Bank, Limited, Threadneedle-street, London, or at the banking house of Messrs. Westendorp and Co., Amsterdam.

Edinburgh.—The Cleaning and Lighting Committee of the Town Council have recommended that the following streets should be lighted by electricity: George-street, St. Andrew-square, South St. David-street, South St. Andrew-street, South Hanover-street, South Frederick-street, South Castle-street, South Charlotte-street, Hope-street, and Charlotte-square.

Harrow.—A meeting of ratepayers has been held respecting the proposed introduction of electric light. The meeting was the outcome of a requisition signed by several large ratepayers and influential persons in Harrow, asking the Board to call a public meeting before proceeding with the electric light. The majority of those present were in favour of electric lighting.

Crystal Palace.—A Committee of the House of Commons has passed a Bill which confirms a provisional order authorising the Crystal Palace District Electric Lighting Company to supply electricity within portions of the district of the Beckenham Local Board, the borough of Croydon, the parishes of Lambeth and St. Giles, Camberwell, and the Lewisham District Board of Works.

Broughty Ferry.—The Northern Electric Supply Company having intimated to the Police Commissioners their desire to lay down an electricity supply service in the burgh, and also that they purpose applying to Parliament for a provisional order to authorise them to do so, the matter has been remitted to the Gas Committee, with power to consult an electrical engineer on the subject.

Kensington.—The Vestry have received notice from Messrs. Jordan and Son, on behalf of the Commercial Electricity Supply Company, of the intention of the company to apply for a provisional order empowering them to supply electricity in various parishes, districts, and extra-parochial places in the Metropolis, including the whole or some part of the parish of St. Mary Abbott, Kensington.

Buxton.—The Local Board have received a letter from Messrs. Baker, Lees, and Postlethwaite, of 22, Great George-street, Westminster, stating that the Bill to confirm the provisional order (electric lighting order) has received the Royal assent. They enclosed an account of their charges and disbursements in the matter, towards which the Board sent them £100, the total cost having been £191. 13s. 10d.

Ladders for Electric Lighting.—The Lancashire and Yorkshire Railway Company has just ordered one of Heathman's patent telescopic ladder towers for the use of the electric light attendants at the Exchange Station, Liverpool. Messrs. Heathman and Co. have also received instructions to build two more ladders for the Great Eastern Railway stations and a portable ladder-carriage for the Bath Electric Light Company.

Newcastle.—The City Lighting Committee of the Corporation on Tuesday received a communication from the Newcastle and Gateshead Gas Company respecting the dispute between the Corporation and the gas company. It was decided to receive the directors of the gas company at a conference, and that the order for several new electric lamps, previously decided upon by the committee, be held over pending the conference.

Ship-Lighting.—The twin-screw steamer "Seaford," which has been built by Messrs William Denny and Bros. for the Newhaven and Dieppe service, is lighted electrically. The generating plant comprises a Chandler engine and Crompton dynamo. The fourth vessel built by Earle's Shipbuilding Company for the Great Eastern Railway Company's continental service, which was launched on Wednesday at Hull, will be equipped with the electric light.

Bolton.—The Gas and Electricity Committee of the Corporation has received an estimate prepared by the electrical engineer of the cost of substituting electric light in place of gas in the large lamp on the Town Hall-square, and it has been decided that the work shall be carried out. The engineer has reported that the applications for current continues to be very satisfactory, there being up to the present 20 consumers, with a total demand of over 2,000 8-c.p. lamps.

Leeds.—A sub-committee of the Highways Committee of the Leeds Corporation have had under consideration the question of laying telephone wires in the city. The committee have accepted the terms offered by the Government for the laying of wires underground in Leeds. The National Telephone Company wish to have further wires in the city, and the committee agreed to let them be laid underground, but at a certain charge per subscriber using the wires. The company, it is said, will consider the matter.

Greenock.—Provost Shankland drew attention at a meeting of Greenock Police Board on Tuesday to a notice submitted by the clerk to the Law and Finance Committee, by the Caledonian Electric Supply Company, Edinburgh, of the intention of that company to apply to the Board of Trade for a provisional order to supply electricity within the districts comprised within the municipal boundaries of Greenock. The clerk was instructed to intimate to the company that the Board of Police would oppose the application if made. It was not desirable, the Provost said, to encourage private companies amongst them.

Portsmouth.—The cables have now been carried through Russell-street, and they will shortly be laid down along the Clarence and South Parades at Southsea. The esplanade is already lighted from pier to pier. Elm-grove Baptist Church has adopted incandescent lamp lighting. For private lighting incandescent lamps are being readily taken up, especially at Southsea. Applications are being received from streets and localities outside of the area to be connected, and when a sufficient number have

Digitized by Google

been received to justify them in moving, the committee will take the necessary steps to extend the cables in other directions.

Shrewsbury.—Among the measures which have passed the House of Commons Committee on the Unopposed Bills is the Electric Lighting Provisional Orders (No. 3) Bill, confirming certain orders relating to the towns of Shrewsbury and Oswestry. The Shrewsbury Electric Lighting Company are on the point of building suitable works in Foundry-square, at the bottom of the Seventy Steps, where operations are to be begun in a month's time. The company have acquired power to supply current throughout the borough.

Direct United States Cable Company, Limited.—The report of this Company for the six months ended June 30 states that the half-year's revenue amounted to £34,843, as compared with £40,836. The expenses, including income tax, amounted to £18,750, leaving a net balance of £16,093, and making, with £3,080 brought forward, a total of £19,173. Three quarterly interim dividends have been paid during the financial year, and a final payment of 2s. per share is now proposed, making 2⅝ per cent. for the year. After transferring £6,000 to the reserve fund, which now stands at £281,551, a balance of £1,031 is carried forward.

Leicester.—The electric light cables are about to be laid for the supply of current for the centre of the town, and the Gas Committee ask those intending to adopt the electric light at once to make application for the same, so that arrangements may be made in laying the cables for the necessary house connections. The charge for current will be 6d. per Board of Trade unit. The Gas Committee anticipate being able to supply the light in the district referred to during the coming autumn, probably by the end of October. The committee are prepared to carry out and supply everything required in connection with house wiring and electric light fitting.

Metropolitan Electric Supply Company, Limited. — This Company is this week issuing £150,000 4½ per cent. first mortgage debentures, at 105 per £100 stock. This stock is redeemable at the Company's option on six months' notice on and after January 1, 1916, at £110 for every £100 stock. The holders of the existing £100,000 5 per cent. registered debentures may exchange their debentures at par for debenture stock of this issue, receiving payment of interest at 5 per cent. accruing from June 1 to the 19th inst. All debentures not presented for conversion will be repaid on, and cease to bear interest at, the expiration of six calendar months.

Brasyer v. Harness and Others.—In this case the jury, after a six days' trial, were only able to answer some of the questions put to them, and whilst a verdict was entered upon the findings for Dr. M'Cully, nothing was done as to the remainder of the first case, nor as to the cross action. Mr. Witt, Q.C., having since then applied to have the case set down for further consideration, Mr. Justice Charles said that he did not see how, under the circumstances, more could be done than had been already done, and thought that to put down the case for further consideration would only be to incur unnecessary expense. Mr. Abinger, who was for Dr. M'Cully, asked for the costs of the day; but the judge declined to accede to the application.

Glasgow.—The Statute Labour Committee reported to the Police Commissioners on Monday that at a meeting of the sub-committee on Glasgow Bridge the clerk submitted an account which he had received from the postmaster and surveyor of the city for the work of diverting underground wires from Glasgow Bridge to the temporary new bridge, etc., by the engineering branch of the Post Office, amounting to £349. 0s. 1d., and the sub-committee having considered the same, and having regard to the Post Office statutes on the point, agreed to recommend that it be passed on to the Statute Labour Committee for payment. Mr. Martin moved, and Bailie Hamilton seconded, the adoption of the minute, which, after some discussion, was carried.

Devonport.—The Highways and Streets Committee recommended the Burgh Council that a contract be entered into with the Devonport Gas Company for supplying the public gas lamps for seven years at the present rate—viz., £3. 7s. 6d. per lamp per annum. The feeling was expressed that in view of the rapid progress being made with electric lighting, the Council ought not to tie their hands for seven years, more especially in view of the letters which had been read at that meeting from electric lighting companies intimating their intention of applying for provisional orders to supply electrical energy. Eventually it was decided that the contract with the gas company should be determinable at the end of the third, fifth, and seven years by six months' notice.

City and South London Railway Company.—The accounts of the City and South London Railway Company show a balance, after providing for the debenture interest and the full dividend on the 5 per cent. preference shares, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of 1 per cent. per annum. A balance of £1,335 is carried forward. The dividend for the corresponding period last year was at the rate of ¾ per cent. per annum, and the balance carried forward £898. The receipts of the Company for the week ended July 15 were £882, against £776 for the corresponding week of 1893, or an increase of £106. The total receipts for the current period of the present half-year amount to £1,761, as against £1,845 in the corresponding period of 1893.

Shoreditch.—The Highways Committee of the London County Council reported on Tuesday that the Vestry of Shoreditch had made an application to the Board of Trade for an extension of the time specified in the Shoreditch Electric Lighting Order, 1892, within which the compulsory works are to be carried out. The Board has intimated that it does not appear to have power to grant the extension asked for, but that the question whether the order shall be revoked on account of non-compliance with its requirements is within the Board's discretion, and that it proposes, subject to any representation which the Council may make, to defer the consideration of this question for 12 months. The committee were of opinion that it is unnecessary for the Council to take any action with reference to the matter.

The Douglas Tramway.—The electric tramway from Douglas to Groudle has been largely patronised during the past week, from 2,000 to 3,000 persons passing over it every day. Dr. Hopkinson is making arrangements for the opening of the line to Laxey. The whole of the electrical plant and machinery is now nearly completed, and it is expected that in a few days a carriage will be sent right through from Douglas to Laxey. The electric tramway company have already received intimation from the Leeds Corporation that a deputation from that body will visit the island for the purpose of inspecting the line and its mode of working, and the secretary of the Tramway Institute of Great Britain has also intimated that the members of that body will visit the island for the same purpose when the line is completed.

County Court Case.—The Abell Electrical Engineering Company, at the St. Helens County Court on Wednesday, sued Robert Pownall, watchmaker, of St. Helens who has lately added farming at Sutton to his operations, for £2. 17s. 6d., the price of an electrical regulator to his incubator. The defendant refused to pay, as he alleged that the regulator had failed in its work and destroyed about 600 eggs. He had attached to his incubator this apparatus, which was to regulate the temperature, instead of which, he submitted, it failed, and the heat rose to about 130deg., spoiling all his eggs Mr. Abell said the regulator had been improperly used, but it could easily be repaired. As the company was now in liquidation, his Honour said they ought to have sued in the name of Mr. Marsh, the liquidator. He, however, non suited with costs.

Windermere.—A notice has been received by the Local Board from the Windermere District Electric Supply Company, intimating their intention to apply for a provisional order. The Clerk, being asked to explain, said the object was to obtain compulsory powers, same as those possessed by the gas and water company, as to breaking up streets. At present they could only proceed by consent. The important thing was to see that the Board got proper clauses for their protection as a public body. The best way would be to leave the matter in the hands of a sub-committee to consider what action to take in the matter. The Chairman said there was another view of the matter. It was a question whether the Board, as a public body, would ever wish to undertake the public lighting themselves, but he did not see that the Board, as a body, would ever wish to take the public lighting.

Grasmere.—At a meeting of the Local Board a letter was read from the Windermere Electric Light Supply Company stating that it was their intention to apply to the Board of Trade before December 21 for a provisional order to authorise the company to supply the electric light within the Grasmere Local Board district, such order to be confirmed in the following session of Parliament. The Chairman said it was a very important question, and if they were of opinion that the work should not be allowed, it would be necessary to oppose the application. Mr. Dixon said that they were well situated as to means to supply the electric light for their own district. If they let the company get a monopoly it would be very expensive buying them out. The other members were of opinion that the Board would do best to supply their own district. It was agreed to let the matter stand over for further consideration.

Aberdeen.—The Watching and Lighting Committee of the Town Council have been informed that the Gas and Electric Committee propose to increase the charge for the electric lighting of the streets from 2¼d. to 3⅜d. per lamp per hour. It is understood that, including the supply of carbons and the expense of cleaning, etc., which will now have to be borne by the lighting department, the total cost will be about 4½d. per hour, and some members were of opinion that it was too much. It has been resolved to endeavour to arrange a joint meeting of the Watching and Lighting and Gas and Electric Committees to consider the matter. The electric light installation at the Northern Co-operative Company's central premises in Loch-street was started last week. The ceremony was performed by Mrs. Doig, wife of the chairman of the company, in presence of the directors. Prof. Kennedy, who had previously tested the installation, congratulated the company on the public spirit they had shown in adopting electric lighting at this early stage of its history.

The Belfast Central Station.—The new central electric lighting station will be situated between Chapel-lane and Marquis-street. There will be an entrance from each of these streets. The entire site is now being piled, sleepered, and sheeted to prepare it for the concrete foundations and floor. The contractors are Messrs. Harvey and M'Laughlin, of Belfast, while the architect is Mr. C. Stanley Peach, F.R.I.B.A., of 8, John-street, Adelphi, London, W.C. The work is being carried out under the superintendence of Mr. V. A. H. M'Cowen, the resident electrical engineer, the clerk of works being Mr. James Moore. The Belfast installation is modelled on that of the Westminster Electric Supply Corporation, of which Prof. Kennedy is the engineer. The chief difference will be the use of gas engines instead of boilers and steam-engines. It is calculated that the total cost of the central-station scheme will be £19,000 exclusive of land, buildings, and meters, but inclusive of the whole of the plant and machinery, mains and roadwork.

Digitized by Google

Ulverston.—An application has been sent to the Local Board by the Windermere and District Electric Lighting Company to supply electric light within the Ulverston Local Board district. Mr. Tosh referred to the Board having obtained powers some years ago for providing electric light in their district, but not having exercised those powers they had got notice that the order had outrun its time, and there had been a communication with Sir Courtney Boyle upon the subject. It was then stated that if any company wanted to assume the powers, notice should be sent, and the local authority should have the first right, and that a new order would cost a few pounds, the idea being that the Board could not play the part of the dog in the manger—neither use the electric light itself, nor allow anyone else to do so. He proposed that the application be referred to the Gas and Water Committee. Mr. Pearson alluded to the former action of the Board, and said no good had resulted from it. He did not think the town was prepared to adopt the electric light. Mr. Atkinson seconded Mr. Tosh's motion, which was carried.

National Telephone Company, Limited.—The report of this Company for the 14 months ending June 30 states that the net result, after deducting Post Office royalties amounting to £73,945, is a profit balance of £316,483, as compared with a balance of £217,725 for the preceding 12 months. An interim dividend at the rate of 6 per cent. per annum on the first and second preference shares and 5 per cent. per annum on the third preference and ordinary shares has already been paid. The Board now recommend a further payment at the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the third preference and ordinary shares, making the dividend for the 14 months at the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the third preference and ordinary shares. They also propose to transfer £63,429 to the reserve fund, so as to bring it up to £225,000, and to carry forward £1,765. Letters of allotment in respect of the issue of £1,10C,000 3½ per cent. debenture stock in the National Telephone Company, Limited, have been posted.

Yarmouth.—At the meeting of the Town Council in committee, to determine the position of the electric light lamps, the surveyor said he proposed to place the lamp-posts in the centre of the carriageway along the drive, where the distribution would be most effectively utilised, the traffic best regulated, and the lighting of the cross roads rendered easier. The centre of the roadway was the usual position for electric lamps where the roads were of sufficient width. Mr. Chamberlin moved that the lamps be placed on the inside kerb of the east footpath, and not in the centre of the roadway, but his proposal was defeated. It was also resolved to place two additional arc lights on the east side of the Beach Gardens. With respect to the position of the lamps Mr. Preece telegraphed that the "taste of the committee should rule the matter." The School of Art is to be repaired and added to. The estimated cost of introducing the electric light in the principal rooms is £130 (or less ventilation which would not be needed if electric light were put in instead of gas, £32. 10s , £97. 10s.). The Council will extend the electric light leads from King-street to the School of Art, at a cost of £30.

The City Electric Inspector.—In connection with this appointment, a correspondent signing himself "Electricity" in the *City Press* writes as follows: "I should esteem it a favour if you would ask the following questions in your next issue, as there appears to be some heartburning about the recent appointment of a City inspector of electric lighting: (1) Whether it is not a fact that the appointment of an electric inspector for the City of London was referred to Mr. Preece, and practically settled by him, instead of by the Commissioners of Sewers? (2) Whether it is not a fact that in the recent competition for this post Mr. Preece, to whom the matter was referred, had not himself given testimonials in support of certain candidates? (3) Whether in such event Mr. Preece was a free arbitrator, and whether it was fair to the other candidates to refer the matter to a gentleman whose testimonials pledged him beforehand to a certain course of action? (4) Whether the Commission of Sewers have not evaded their duty by referring the matter to anybody, instead of settling it themselves, and, further, whether such a course of action does not amount to a confession that they were unfit to make the appointment of such an official?"

Mullingar.—The Board of Guardians have received the following letter from Mr. M. J. Hackett, solicitor, 47, Lower Sackville-street, Dublin: "In conformity with the requirements of the Electric Light Act, 1882 and 1888, and the rules made by the Board of Trade with respect to applications for provisional orders, I hereby give you notice that application is intended to be made to the Board of Trade on or before the 21st day of December next by the Irish Electrical Supply Company, Limited, whose registered office is situated at 47, Lower Sackville-street, Dublin, for a provisional order to be confirmed in Parliament in the ensuing session, whereby it is proposed to authorise the said company to construct works and produce, store, supply, and sell electricity for lighting, motive power, and all public and private purposes within the borough or district of Mullingar. I shall be glad to be informed that the local authority assents to the proposed application to the Board of Trade and to be furnished in due course with a certificate signed by you reciting copies of the notice, and of the resolution, and declaring that the notice was duly given and the resolution passed as required by the said rule." No order has been made on the subject by the Board of Guardians.

Worcester.—At a meeting of the Town Council the Mayor proposed that the Watch Committee should be authorised to organise an exhibition of electrical appliances, etc., in the Public Hall, for about one week in the middle of October next. Mr. Williamson stated that at that time the committee would be prepared to supply the electrical energy to any consumers along the line of route of the mains, and by that time, or the early part of next year, the Council would be involved in an expenditure of about £4,000 a year in the payment of principal and interest and establishment charges. It therefore behoved them to get as much of the current used as they could this year, and to "keep pegging away" until they got the whole of the energy produced into commercial use. If they had an exhibition they would get all the leading manufacturers of the kingdom to exhibit fittings, lamps, meters, motors on a small scale, and all kinds of apparatus. They hoped to have the Public Hall lighted by electricity at that time, and to show to the people of Worcester the advantage of taking the light. The proposal was agreed to, it being stipulated that the expenses should be limited to £50, not to include the hire of the room or the supply of the current from Powick.

Stafford.—In moving the adoption of the report of the Electric Lighting Committee of the Town Council, Alderman W. H. Peach said they recommended the acceptance of the General Iron Foundry Company's tender for the supply of wrought-iron mitred jointed window frames, this being the lowest. Five tenders were received for an overhead traveller to lift eight tons with a span of 45ft. The highest tender was £225, and the lowest £160. The engineer recommended the tender of Mr. T. Smith, of Rodley, whose traveller appeared the most suitable, for £185. Dr. Hopkinson recommended the acceptance of the tender of Maignen's Filter Company's apparatus to be erected at a cost of £220 in order that the water used for the steam-boilers might be filtered and softened previous to use, it being proposed to apply the river water for the purpose of providing water for the boilers. Mr. Peach explained that to use the Corporation water would entail a cost of £359, the quantity required being large, whilst the river water, yielding an ample supply, would only need softening to assist its condensation. He added that it was proposed by the committee in connection with the erection of the electric lighting station that a commemoration-stone should be laid by the Mayor. It has been arranged to transfer £15,000 from the loan suspense account to the electric lighting account on September 30, and to issue debentures for that amount. The report was carried.

Lighting at Cardiff.—Mr. W. H. Massey, the electrical engineer, informed the Corporation Lighting Committee on Tuesday that the whole of the high-tension cables and the telephone wires had now been drawn in by the Silvertown people, whose men had also made most of the important joints, and the jointing of low-tension and arc light mains was being proceeded with. The work at the station had gone on rather slowly, and, after consultation with Mr. Harpur, the borough engineer, he suggested at the special meeting of the sub-committee that Mr. Fletcher should be temporarily transferred from his service to that of the Corporation, so that he might directly act with Mr. Harpur in little matters which were constantly cropping up, and about which complications might otherwise arise between the Corporation fitters and the contractors. The main switchboard had arrived, and preparations were being made for fixing it in position. The fourth dynamo bed was in place and he hoped that before the end of the week all the engines would be so far erected that the exhaust-pipes could be obtained. Messrs. Siemens had decided to fit new and improved flexible couplings between the engines and dynamos, and some little delay had in consequence taken place. The appointment of Mr. Fletcher, as recommended by Mr. Massey, was agreed to, at a salary of £16 a month. A local paper states that lighting will not commence until the early part of September. The price to be charged will be 6d. per Board of Trade unit.

Woodhouse and Rawson United, Limited, v. Jolin.—In this case, heard in the City of London Court, the plaintiff company claimed the sum of £8. 11s. 9d. for goods supplied to the defendants, Messrs. Jolin and Co., of Bristol. Mr. William Hicks, the solicitor for the plaintiffs, said that the claim was not in dispute, but the defendants had raised a counterclaim for goods supplied by them to the plaintiffs for a larger sum. The goods which were subject-matter of the counterclaim were supplied after Mr. F. D. Leslie had been appointed by the Chancery Division of the High Court as receiver of the plaintiff company's business, with liberty to carry on the business. The question for the Court to decide was whether the defendants were entitled to set up against the receiver a claim which he could only prove against the company, it being in liquidation. It might be hard upon the defendants, but that was no reason why the receiver should have to deal with the counterclaim. The learned Commissioner said that if the defendants did not know that they were dealing with the receiver (and that was admitted) then there was no contract with the receiver. Mr. Hicks said the receiver was acting on behalf of secured creditors who were mortgagees in possession practically. The point was whether an unsecured creditor of a company could set up his claim against a secured creditor. The learned Commissioner said the point was a very fine one. He non-suited the plaintiffs, but as there were many more cases depending upon it he would give them leave to appeal, so that they might raise the question elsewhere.

Canterbury.—The following letter, received from Messrs. Mowll and Mowll, 73, Castle-street, Canterbury, has been read at a meeting of the Town Council: "The committee appointed at the public meeting, held the other day, with reference to the introduction of the electric light into Canterbury, are desirous of ascertaining from the Corporation the amount of street and public lighting the Corporation will give to the company if the works are carried out and the light supplied. As the Corporation are probably aware, the Brush Company are willing to subscribe £12,000 if a sum of £6,000 is subscribed for locally. Before

Digitized by Google

taking steps to ascertain whether they are in a position to obtain this capital the committee are, of course, anxious to know the amount of custom they are likely to receive from the authorities of the city." The Town Clerk reminded the meeting that at the last Council meeting he was instructed to affix the corporate seal to a contract with the gas company for one year. Councillor Lukey said he would like to know what decision was come to when it was decided that a provisional order be obtained. Was not there a plan of the district over which it was proposed the electric light should be carried? Councillor Harris stated that Mr. Garcke estimated to be able to light the city by means of 125 lamps at a cost of £2,700, but they showed him that would be impossible. Then a question arose as to what number of lamps the Council could take, and they gave the company to understand that they could not take any. The reason was that if they had 20 electric lamps the gas bill would not be appreciably reduced, because the gas standards would still be needed. The matter ultimately dropped.

Windsor.—At a meeting of the Town Council the following report from the Electric Lighting Committee was read: "(1) Your committee report that the town clerk has made enquiries of upwards of 80 other boroughs and places where the town council or other local authority have themselves obtained provisional orders for the supply of electric light and power, and he has also attended at the office of the Board of Trade and made enquiries there, and has obtained much valuable information which has been placed at the service of your committee. (2) Your committee, considering that it was of great importance that the adjoining towns of Windsor and Eton should act in unison together, and being also unanimously of opinion that the supply of electricity can be carried into effect more economically and with greater certainty of financial success by the inclusion of Eton and Eton College in the scheme, have put themselves into communication with the Eton Local Board, and have met a committee appointed by the Board in conference when the subject was fully discussed, and your committee have since received from the Eton Local Board the following resolution—viz., 'This Board is willing to acquiesce in allowing Windsor to obtain a provisional order for lighting Eton with electricity, supposing satisfactory terms can be agreed upon.' (3) Your committee recommend that the Town Council apply to the Board of Trade to revoke the Windsor Electric Lighting Order of 1890, which your committee are advised is the first step necessary to be taken. (4) Your committee also recommend the Town Council to apply to the Board of Trade for a provisional order to supply electric light and power for public and private purposes within the borough, and also within the district of the Eton Local Board. (5) Your committee ask the Council to grant to them authority to employ an electric engineer, to advise and report upon the subject." The report was adopted.

Appointments Vacant.—The Corporation of Derby invite applications for the position of assistant engineer. Applicant must have had experience of high speed engines, condensers, alternators, arc lamps, and have served time as a fitter. Applications, with three recent testimonials, are to be addressed to Mr. J. E. Stewart, engineer and manager, Electric Light Station, Full-street, Derby, by to-morrow (Saturday).—The Governors of the People's Palace will shortly appoint for their evening classes a head of the electrical department, who will be expected to give all his evenings to the work of the department The salary offered is £150. Applications are to be sent to the director of evening classes, People's Palace, London. E —An assistant master for physics and elementary mathematics, and an assistant master for physics and electrical engineering are required for the municipal technical schools at Hull. The salary offered in each case is £120 per annum, and applications are to be sent to Mr. J. T. Riley, Town Hall, Hull, by Tuesday next.—The South-West London Polytechnic require, by the 28th inst., a principal to undertake direction of the whole educational work, the higher teaching in at least one department of science, and head-masterships of day schools. The salary offered, from April 1, 1895, is £600 per annum. Meanwhile the successful candidate will be expected to advise governing body as to equipment, etc., and occasionally visit building in course of erection, from time of appointment, for an honorarium of £100. Forms of application may be obtained from Mr. F. P. Murray, secretary to the governing body, 47, Duke-street, St. James's, S.W.—The Plymouth Technical Instruction Committee invite, by August 1, applications for the appointment of head master of the science, technological, and commercial department of their science, art, and technical schools. He must hold a university degree, and be highly qualified in chemistry, physics, and mechanical subjects. The salary is £300 per annum.

Bath.—The Town Council have received a notice from the electric lighting company stating that they intended to apply to the Board of Trade for a provisional order extending their work for private and public lighting to any place within the city of Bath. The Clerk added that this notice was served on June 30. The Act required that it should be served before July 1 The Chairman: What time must elapse before the company can take another step? The Clerk said they must present a memorial to the Board of Trade, and must advertise their application in a local paper two consecutive weeks. This notice would show the extent to which they applied. The committee would probably like to know how the matter stood at present. The company now derived its power from the Board of Trade by a license which was granted about three years ago. This license gave the company the power to carry out their electric lighting over certain specified areas for seven years from the date of the license, and in the license there was a provision that at the expiration of the seven years the urban authority had the power of purchasing the whole of the works if they thought fit, either by agreement or, if they could not agree, by arbitration. This provisional order would not be sanctioned by the Board of Trade except with the consent of the authority, and if it were granted it would give the company 21 years from the date of the provisional order within which they might carry out their work. Not only would it very much extend the time they now had, but it would include the whole of the district, whereas their license at present only extended to the area which was now lighted by electricity. In this case, of course, the authority would then not be able to entertain any application by any other company, as they now might, with respect to that part of the district not included in the present electric area. Alderman Sturges said the matter had been before the Lighting Committee in a very cursory manner. They did not feel called upon to accede to the terms of the electric lighting company, but they were extremely anxious to do justice on both sides They wanted to look at the question in all its bearings, and therefore he moved that it be sent to the Electric Lighting Committee, who would bring up a report. This was agreed to.

Electric Pumping Plant.—Messrs. Ernest Scott and Mountain, Limited, Newcastle, have completed for Messrs. Strakers and Love, Brancepeth Colliery, an electric pumping plant, which is capable of delivering 300 gallons of water per minute through two miles of 6in. pipe against a head of 250ft. Owing to the friction in the pipes this equals a total head of 410ft. The installation consists of a set of three-throw ram pumps driven by an electric motor. The current is generated by a Tyne compound-wound dynamo capable of giving an output of 55 units, and is driven by a horizontal steam-engine developing 80 b.h.p. The engine is of the horizontal single-cylinder long-stroke type, capable of developing 100 i.h.p., or 80 b.h.p., with a steam pressure of 40lb. per square inch. The cylinder is 23½in. diameter by 33in. stroke. The dynamo is of Messrs. Scott and Mountain's improved mining type, capable of giving an output of 60 units—*i.e.*, 120 amperes at an E.M.F. of 500 volts—when running at a speed of 550 revolutions per minute. The armature is of an improved type, constructed to admit perfect ventilation and ready repair in case of accident. The dynamo is mounted on a cast-iron sliding bedplate, with tightening screws and brackets enabling the slack of the belt to be taken up whilst the machine is running. The switchboard consists of one double-pole switch with double-pole cut-outs provided for switching on and off the current to the pumps, and is fitted with Scott and Mountain's improved sparking contacts, preventing the metal surfaces of the switch being injured by sparking; one voltmeter to read to 600 volts, with measuring key; and one ampere-meter to read to 150 amperes, with measuring plug. The conducting cables between the main switchboard and the pumps consists of 1,300 yards of stranded high-conductivity copper cable, composed of seven wires No. 11 B.W.G. This cable is supported on poles with oil insulators. The pumping plant is placed at a distance from the engine-house of 700 yards. The pumps are capable of delivering 300 gallons of water per minute against a head of 410ft. when running at a speed of approximately 36 strokes per minute. They are the three-throw ram type with rams 9in. diameter by 15in. stroke The electric motor is capable of giving 55 effective horse-power when running at a speed of approximately 600 revolutions per minute. In general design the machine is similar to the dynamo, but the bedplate is extended and two additional bearings are fitted, and on the extension to the shaft two driving pulleys are placed running between main bearings, and from these pulleys the power is transmitted to the pumps. The motor is mounted upon a cast-iron sliding bedplate fitted with tightening screws and brackets, so that the slack of the belt can be taken up whilst running. A main starting switch is provided, so that the motor can be stopped or started slowly, and all shock taken off the pumps.

St. Pancras.—The Finance Committee of the London County Council made the following report on Tuesday: "We have considered the application from the Vestry of St. Pancras for a further loan of £14,600 for 42 years, on the annuity system, for electric lighting purposes. On July 25, 1893, we reported on the Vestry's application for a loan of £30,000 for electric lighting works, when we recommended (having regard to the amount already borrowed—viz., £10,000—and £8 000 for sites, and £60,000 for works, and to the circumstances referred to in our report) that the loan should be limited to £15.400 The Council concurred in our recommendation and agreed that the repayment should be spread over 42 years. This loan was not taken up at that time. On February 13, 1894, we reported very fully on a renewed application for the loan of £30,000, in which application the Vestry asked that the order sanctioning the borrowing of the £15,400 should be cancelled, and the Council on our recommendation directed that the resolution of July 25, 1893, sanctioning the borrowing of £15,400 for 42 years should not be further acted upon, and in lieu thereof sanctioned a loan of £29,700 (inclusive of the £15,400 previously sanctioned), to be repaid in 25 years. This resolution was communicated to the Vestry on February 16, and we have just been informed that the Vestry, on March 30, notwithstanding this intimation and without notice to the Council, borrowed elsewhere the sum of £15,400, thereby ignoring the last resolution of the Council, and assuming that the previous sanction for raising £15,400 repayable in 42 years, although withdrawn, was effectual; and they now ask consent to borrow £14,600 for 42 years, making up the original £30,000, in place of the £29,700 dealt with by the Council as above stated. In view of the Council's decision of June 26 lost in the case of the Hampstead Vestry, allowing 42 years for repayment of a loan of £24,400 for the cost of initial electric lighting works,

Digitized by Google

and in deference to the opinion of the Council as expressed in that case we are now recommending that a period of 42 years should be allowed for the proposed loan to the Vestry of St. Pancras. As the Vestry has taken up a loan for the £15,400, the resolution of the Council of February 13 conditionally sanctioning the Vestry borrowing £29,700 should be withdrawn, and a substituted resolution passed limiting the loan to £14,300, making with the £15,400 borrowed the sum of £29,700, the amount to which we previously recommended the loan should be limited. We accordingly recommend (*a*): That the resolution of the Council of February 13, 1894, agreeing to advance to the Vestry of St. Pancras the sum of £29,700 for works for electric lighting purposes, be not further acted upon. (*b*) That, subject to the Council hereafter giving its written consent under seal to the borrowing, and subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of St. Pancras for a loan of £14,600 towards defraying the cost of electric lighting works in the parish be granted, to the extent of £14,300, on condition that the loan be taken up at once, interest being charged thereon at the rate of £3 10s. per cent. per annum, calculated quarterly, and with the principal being repaid by such equal half-yearly payments of principal and interest combined as will repay the amount borrowed within a period of 42 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the consolidated loans fund." This report was adopted by the Council.

PROVISIONAL PATENTS, 1894.

JULY 9.

13216. **Magnetic separator.** William Henry Ryder and James Insole Ryder, 36, Slaney-street, Birmingham.

13259. **Improvements in automatic electric exchange** Robert Pippette. 51, Upper Tulse-hill, Brixton-hill, London.

13267. **Improvements in galvanometers.** John Hopkinson, 5, Victoria-street, Westminster.

13286. **Improvements in electrical apparatus for stopping horses.** Carl Pack, 40, Chancery-lane, London.

JULY 10.

13319 **Improvements in electric arc lamps.** Peter Kirkegaard, 70 Market-street, Manchester. (Complete specification.)

13331. **An electrically-controlled lubricating device.** Lancelot Walter de Grave, 24, Crompton-street, Derby.

13358. **Improvements relating to electrolysis, and to apparatus therefor.** Henry Harris Lake, 45, Southampton buildings, Chancery-lane, London. (Isaiah Lewis Roberts, United States.) (Complete specification.)

13363. **An improved plate for secondary voltaic batteries.** William Alfred Baxter Buckland, 28 Southampton-buildings, Chancery-lane, London. (Complete specification.)

13377. **Improvements in process and apparatus for electrolytically treating salts in solution or in molten state.** Peter Jensen, 77, Chancery-lane, London. (Henrik Christian Fredrik Störmer, Norway.) (Complete specification.)

JULY 11.

13410. **Improvements in electrical switches.** Charles Mark Dorman and Reginald Arthur Smith Ordsal Electrical Works, Salford, Manchester (Complete specification.)

13416. **Continuous electric brakes for railway trains.** Alexander Young, 2, Merchiston Bank terrace, Edinburgh.

13422. **Improvements in or connected with electric relays.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Eugène Maréchal, Pierre Claude Henri Rigollet, and the Société E. Ducretet and L Lejeune, France)

13433. **Improvements relating to electric telegraphy** Claude Joseph Augustin Munier, 6, Bream's buildings, Chancery-lane, London.

JULY 12

13478. **Electric arc hood.** Sidney George Brown, 22, Hamlet-road, Chelmsford.

13499. **Improvements in process and apparatus for electrolytical decomposition of alkali salts** Alf Sinding-Larsen, 77, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883 sec. 103, December 12, 1893, being date of application in Norway.) (Complete specification.)

13523. **Improvements connected with reflectors for electric arc lamps.** Carl Coerper, 166, Fleet-street, London. (Complete specification.)

JULY 13.

13549. **Improvements in apparatus for working electric tramways by means of underground cables.** Chris Anderson, Lane House, Jack-lane, Hunslet, Leeds

13550. **Improvements in apparatus for working electric tramways.** Chris Anderson, Lane House, Jack-lane, Hunslet, Leeds.

13579. **Improvements in coin-controlled electrical apparatus.** John Orlando Frost, 323, High Holborn, London. (Date applied for under Patents, etc, Act, sec. 103, December 30, 1893, being date of application in United States.) (Complete specification.)

13568. **An improved combined electric switch and regulator.** Francis Tallack, Francis William Tallack, and Louis Héndlé, 10, Great Turnstile, Holborn, London.

13581. **Improvements in electric cables.** Silvanus Phillips Thompson, 6, Lord-street, Liverpool (Date applied for under Patents, etc., Act, 1883, sec. 103, December 19, 1893, being date of application in United States.)

13594 **Improvements relating to the insulation of wires for electric heating apparatus.** Hugo Helberger, 18, Buckingham-street, Strand, London.

JULY 14.

13623 **An invisible electric switch and bracket combination.** Thomas Ernest Waltham, Chapel-place Works, Great Chapel-street, Westminster.

13634. **Improvements in arc lamps.** James William Rogers, 37, Cursitor-street, Chancery-lane, London.

13636. **Improvements in perforators used for transmitting telegraphic messages and cablegrams.** Henry Whawell, 11, Aldebert-terrace, Clapham-road, London.

SPECIFICATIONS PUBLISHED.

1886.

NOTES.

Western Australia.—The Ministry propose to extend the telegraph system.

Saint Chamond.—A local company has been formed to supply electric light and to transmit power.

Electric Lighting at Waldenburg.—A scheme has been projected for lighting this town electrically.

Cliff-Lighting.—The North Cliff at Bridlington Quay was lighted by electricity for the first time on Saturday.

Electric Traction at Baden, Austria.—A trial run has been made on the new electric tramway here with success.

Ship-Lighting.—The "Ceylon," built for the Peninsular and Oriential Steam Navigation Company, is lighted by electricity.

New South Wales.—An experimental electric tramcar is running regularly between Bridge-street, Sydney, and the Redfern terminus.

Electric Organs.—Those interested in the subject of electric organs will find an illustrated article dealing with them in *Cosmos* of July 23.

Cambridge.—The Cambridge Electric Supply Company will give on October 8 an uninterrupted supply of current at all hours of the day and night.

Electric Lighting at Stuttgart.—Work has been commenced by Messrs. Schuckert and Co. on the erection of a central electric lighting station here.

Electric Lighting of Urbeis.—Mr. Karl Amel intends to utilise the water power of the falls at Urbeis, Alsace, for electric lighting and power purposes.

Cable Communication.—The Eastern Telegraph Company state that the Sierra Leone Accra cable is repaired, thus restoring communication by that route.

Telephony in Austria.—Telephonic communication is to be established between Vienna and Linz by autumn. In the course of next year the line will be extended to Salzburg.

Electric Lighting at Schneidemuhl.—Messrs. Schuckert and Co. propose to erect a central electric light station here. The mechanical plant will be supplied by Mr. H. Panksch, of Landsberg.

Electric Power at Lagerdorf.—An electric installation, on the rotary-current system, has been carried out by the Allgemeine Elektricitats Gesellschaft at the Breitenburg Portland Cement Works, near Itzehoe.

Electric Lighting at Helmstedt.—The local clay works are being supplied with an electric light installation by Messrs. Schuckert and Co., of Nuremberg. There are 200 incandescent lamps and four arc lamps.

Electric Traction in France.—The Compagnie Nationale d'Electricité has under consideration the introduction of electric traction on tramways in those towns where they have established central stations.

Hanley Central Station.—This central station was to be set in operation yesterday (Thursday) evening by the Mayor (Mr. E. J. Hammersley). The Brush Electrical Engineering Company have carried out the work.

Central Electric Station at Furth.—A central station is to be erected here for the supply of current for lighting and power purposes. The station will be built to be able to supply 1,000 16-c.p. incandescent lamps.

Electric Power in a Factory.—The firm of M. Joseph and Co., of Plauen, who are manufacturers of trimming, are erecting new works at Stuttgart where the machinery is to be driven by means of electric motors.

Grunberg (Silesia).—The water power of the Bober at Christianstadt will be used by Mr. Sothmann for an electrical plant for the transmission of current for lighting and power purposes at Grünberg. About 350 h.p. is available.

French Lighthouses.—The lighthouses on the Isle of Yeu in Vendee is about to be equipped with an electric light, which is to be of large illuminating powers, and to flash at intervals of five seconds. The light will be visible in clear weather a distance of 52 miles.

Electric Lighting at Tutzing.—Count von Landberg Hallberger has erected a central electric supply station at Tutzing. The castle, two hotels, and a brewery are connected, and negotiations are in progress for lighting the railway station, post office, and streets.

A "Laberatorium."—A French contemporary regards as an important institution a laboratory that has been established at 49, Rue d'Amsterdam, Paris. The "laboratorium" is provided with all kinds of motive power, and analyses and industrial investigations will be undertaken.

Electric Lighting at Trent.—The local authorities of Pergine, near Trent, have erected a central electricity station, and over 100 h.p. is being used for electric motors. The price charged for a 5-c.p. incandescent lamp is 4s. 7d. per year, and the wiring is undertaken by the authorities.

Telephony in France.—The number of subscribers to the telephone in France was 11,440 on September 1, 1889, 6,255 being in Paris, and the remainder in the provinces. On May 1, 1894, the total had increased to 25,858, of which 13,060 were in the capital, and the remainder in the provinces.

Electric Traction in Berlin.—In connection with the exhibition to be held in the Treptow Park in 1896 the Berlin Horse Tramway Company propose to build an electric tramway from Berlin to the park. A scheme is also on foot for the construction of an underground electric railway between Stralau and Treptow.

Electrical Exhibition at Ealing.—As will be seen from our "Business Notes," the Ealing Local Board have decided to hold an electrical exhibition during October, by which time the central electric light station will be in operation. The exhibition is, of course, intended to popularise the various applications of electricity.

A Moot Point.—Youth (standing with open eyes in respectful awe) to Great Traveller: "Did you ever catch an electric eel, Mr. Gadder?" Great Traveller: "Well, now, I wouldn't like to answer that question off-hand. I had an experience with an electric eel once; but whether I caught it, or whether it caught me, is a matter that was never settled satisfactorily to my own mind."

Fatalities.—"Another Fatality from Electricity" is the heading which the *Journal of Gas Lighting* gives to a paragraph. If we went on the same lines a few columns would have to be devoted each week to the fatal results, explosions, conflagrations, suffocations, etc., due to the use of coal gas, in which the gentleman who searches for an escape of gas with a lighted candle would be well to the front.

City and Guilds of London Institute.—The matriculation examination of the Central Technical College will be held on September 17-20, and the entrance examination of the Day Department of the Technical College, Finsbury, on September 18. The matriculation examination of the City and Guilds Central College will be held on September 17-20, and the new session will commence on October 2.

Electric Motors. — The Hohenzollern Locomotive Works of Düsseldorf have been using electromotors in their pattern shop and foundry since November last. A comparison of the expenses under these conditions with those preceding has proved so favourable to the new system, that the company intend to use electric power in the whole of their works. The estimated saving amounts to £1,000 a year.

Lighthouse Illumination. — The United States Lighthouse Board are arranging, as mentioned in our last issue, to place a powerful light on the Fire Island approach to Sandy Hook, the first land usually made by vessels arriving at New York. It is stated that it will be a Lepante lens with a light of 250,000,000 c.p. placed at an elevation of 168ft., revolving and flashing every 10 seconds, and visible to a vessel 140 miles from New York.

The Douglas Electric Tramway.—This tramway, to which we have referred from time to time, has been completed by the Isle of Man Tramways and Electric Power Company along the coast between Douglas and Laxey, a distance of eight miles. The first trial car was run through on Saturday. Dr. Hopkinson, who is a director of the company, was in charge of the trial, which was a complete success. The Board of Trade inspection is to take place to-day (Friday).

Direct-Current Dynamos.—The graphical solution of some practical questions in regard to direct-current dynamos is discussed by Mr. J. Fischer-Hinnen, of Oerlikon, in the *Elektrotechnische Zeitschrift* of July 19. After dealing with the form of the characteristic, the author passes on to consider the determination of the diminution in pressure of shunt machines. He next treats of the electrical transmission of power by means of two series dynamos and calculations regarding tramway motors.

Self-Contained Vehicles.—We referred in our issue of June 1 to the competition of self-contained vehicles, which had been promoted by the *Petit Journal* of Paris. The final race took place on Sunday between Paris and Rouen, after a weeding out process had been gone through. There were originally five electric carriages entered, one of which was of English make, but four of these, including the last named, were withdrawn. The Comte de Dixon was declared the winner. He did the journey of 128 kilometres in 9 hours 40 minutes, including stoppages.

Electricity in France.—At the close of the past year there were in France 321 central electric light stations at work and 38 in course of erection. There were 127 stations operated solely by water power to the extent of 6,615 h.p.; 114 stations operated solely by steam-engines to the extent of 10,527 h.p.; 33 stations operated both by water and steam power to the extent of 2,911 h.p. of the former and 2,095 h.p. of the latter; and nine stations operated solely by gas-engines to the extent of 396 h.p. There were also several stations using both gas and water power to the extent of 355 h.p. of the former and 715 h.p. of the latter.

A Curious Perversion.—In a note in our issue of June 15 we gave the following item: "It appears that the members of the Italian fire brigade are very prompt in responding to alarms of fire. According to an illustration in *L'Elettricità*, the firemen arrive at houses struck by lightning before the lightning flashes disappear from view." This now crops up in the *Electrical Age* (U.S.A.) in the following deceptive form: "The Best Fire Department.—It is stated that the members of an Italian fire brigade are so quick in responding to a fire call that, in one instance, where a house had been struck by lightning, the firemen arrived before the flash had disappeared."

A Peculiar Accident.—An unusual electrical accident, which recently occurred at the Norfolk Navy Yard, appears to have been explained, and with the explanation comes the necessity of making provision to ground steel or iron vessels that are in dry dock, especially during the season of electrical storms. The *Electrical Review* of New York states that two men standing in water under the vessel, which was insulated by its supports of dry wood, were apparently struck by lightning, although men on the deck of the vessel felt no shock. One of the men was killed instantly and the other died in a few hours. The explanation now given is that the vessel was not struck by lightning in the ordinary sense, but that it acted as an enormous condenser. As it was insulated from the ground it became heavily charged, and was discharged through the men when they, standing in the water and thus making a good ground, touched the metal sides. The remedy will be to ground such vessels while they are in dry dock.

Lighting Power of Incandescent Lamps.—A lecture was recently delivered by M. Larnaude before the Société Internationale des Electriciens in Paris on the subject of incandescent lamps. The lecturer, who is the manager of the Société Générale Incandescente Edison, dealt first with the improvements made in the manufacture of this type of lamp, and stated that it is easy to understand whether there is any advantage in using lamps run economically with a short life. As an instance he gives the following comparative table, which is based on the unit price of 1f. per lamp and on the corresponding lives at different conditions of working the lamps:

1,200 hours for lamps of 4 watts per candle.
800 " " 3·5 "
400 " " 3 "

Cost per kilo-watt-hour in francs.	Cost price per 16-candle lamp hour in centimes. 4 watts per candle.	3·5 watts per candle.	3 watts per candle.
·50f.	3·28c.	2 92c.	2·65
·75f.	4·88c.	4·32c.	3·85
1·00f.	6·48c.	5·72c.	5·05

Manual of the Electrical Company, Limited.—A substantial volume has been issued by the Electrical Company, Limited, 122 and 124, Charing Cross-road, W.C. In the first place, there is a general treatise on electric lighting projects in which rules are given for the distribution of light, and an arrangement of storage batteries is shown, as well as details of wiring, fixing engines and boilers, and there is also a view of a complete generating plant. The transmission of power is dealt with, and plans are given of an electric lighting and power plant installed in a factory. We next have directions for preparing approximate estimates, and other sections treat of continuous-current machines and accessories, of switchboards and instruments, conductors, cables, etc., safety fuses and safety plugs, switches and circuit connectors, installation and insulation material, arc lamps and accessories, incandescent lamp fittings and electroliers, A. E. G. incandescent lamps, and of electric motors. In the last section there are illustrated descriptions of a piston pump driven by electricity, a circular pump, a ventilator, a portable drilling machine, a radial drilling machine, a lathe, lift, travelling crane, and a jib crane worked by means of electric motors. The manual is well got up, and forms a valuable compilation.

The Junior Engineering Society.—The members of this society recently visited the electric and hydraulic installations of the Great Eastern Railway at and in the

Digitized by Google

neighbourhood of Liverpool-street by permission of the engineer, Mr. John Wilson, on whose behalf the district engineer, Mr. H. Wilmer, received the party and superintended the arrangements for their guidance over the extensive area included in the visit. The electric lighting station, situated in Norton Folgate, contains three 100 h.p. and four 200-h.p. compound vertical steam-engines, each driving a dynamo. Steam is supplied by five Lancashire boilers, working at 140lb. pressure. The lights will consist of 212 arc lamps, and 4,773 16-c.p., 272 32-c.p., and 55 50-cp. incandescent. The hydraulic engines and pumps, of which there are two sets, are placed at Bishopsgate-street low-level station, and to meet the demand occasioned by the extension of the system are about to be duplicated, as are also the two boilers and accumulator, etc. There are numerous capstans, truck hoists, parcels lifts, and cranes operated throughout the passenger stations and goods yards and warehouses, and a 50ft. diameter engine turntable has lately been connected up to be worked by hydraulic power. At the conclusion of the inspection Mr. W. H. Le Rittar, member of council, expressed the members' acknowledgments for the reception accorded them on the occasion.

Overhead Electric Railways.—The Americans are beginning to recognise the practical and commercial importance of overhead electric railways, and this is no doubt due to the success of our Liverpool line. Having derived as a commencement some experience from the intramural railway at the Chicago Exhibition, it has now been decided to operate the West Side Elevated Railway at Chicago by electric power. The West Side line, which connects that part of Chicago with the main city transit systems, is to be a four-track line for a greater part of the way, so as to allow of an express service. The power is to be obtained from four dynamos. Two of these are to be of 2,000 h.p. each, and the two smaller dynamos are to be of 1,000 h.p. The current will be conveyed from the generating station over the line by means of a "third rail" placed at the outside of each service track. A sliding shoe contact, hanging from the truck of each motor-car will pick up the current for the operation of the motors. It is intended to fit two motors only to each motor-car at first, but eventually two additional motors will be placed on each motor-car. With the two-motor motor-cars, four car trains will be run during the crowded hours of the morning and evening, and three car trains during the hours of slack travel, at a speed of 13 miles an hour, including stops. With the four-motor motor-cars, the trains will consist of six cars, and the speed will be increased to 15 miles an hour.

The Elevated Electric Railway in Berlin.—It is now some time since any information of real value has been forthcoming concerning the proposal to construct an elevated electric railway in Berlin from the Warschau Bridge to the Zoological Gardens, and about which we have kept our readers well informed as occasion has arisen. It now appears, however, that a definite scheme has been laid before the Municipal Council by the magistrate, and the consideration of the project has been referred to a committee. According to the proposed agreement to be entered into between the town and Messrs. Siemens and Halske, the former grants to the latter permission to utilise the streets and ways for the purpose of constructing the projected railway. The concession is to be given for 90 years, and in return Messrs. Siemens and Halske will pay to the town a percentage of the annual gross receipts from passenger and goods traffic, or on the former alone should there be no transport of merchandise. The percentage will range from 2 per cent. on an income of £300,000 to £350,000 to 4 per cent. on a revenue of £800,000 or over. The railway, which is to be completed and set in operation within four years from the date of the concession, is to provide a five minutes' service, and the line may be acquired by the town at certain periods during the duration of the concession. Connection is to be made with local lines and wagons from the latter must be conveyed over the electric railway.

Pure Water and its Electric Resistance.—Until recently the purest sample of water that has been physically examined was that obtained by Prof. F. Kohlrausch by distillation in vacuo, and which showed an electric conductivity only one-third of that of water distilled under atmospheric contact. The *Engineer* states that such low conductivity only endured for a short time, owing to the water taking up foreign matter from the sides of the containing vessel of the electrodes. The distilling apparatus used on that occasion, after standing full of water for nearly 10 years, has lately been used by Messrs. Kohlrausch and A. Heydweiller in some new experiments, which have been described in the *Transactions* of the Academy of Sciences at Berlin. The water obtained has, when tested at 18deg. C., only one-sixth of the conductivity of the former sample; the resistance of one square millimetre at the freezing point being the same as that of a copper conductor of the same section, 25,000,000 miles long, or more than a thousand times the circumference of the earth. The foreign matters contained in this water only amount to a few thousandths of a milligramme in the litre.

Lighting in Australia.—It is stated in a recent report that the New South Wales Parliament have thrown out every Bill promoted by private companies to light Sydney by electricity on the ground that such powers ought to belong solely to the Corporation. A report to the Adelaide City Council by Mr. George Anderson, C.E., of that city, shows that the Corporation of Melbourne have an Act empowering them to light the streets; the necessary buildings are finished, and the plant has arrived. The gas lamps will be extinguished, and several hundreds of pounds are expected to be saved out of the cost of the present lighting. In all the busy streets of the city electric lights are used, besides all the principal shops and many of the public buildings. In Sydney similar progress is recorded, where the main streets, wharves, railway stations, arcades, theatres, hotels, refreshment-rooms, and shops are all lighted by electricity. All the installations are in the hands of private individuals. Brisbane has also made a beginning now: Queen-street and its shops are lighted by a private firm. The report states that the price charged in Victoria for an incandescent light of 20 c.p. varies from 6d. in some country towns to 1s. 6d. a week in Melbourne. In Sydney the price is 1s. per week, and in Brisbane, where there is no competition, the price is 1s. 9d. per week. On the average the price is 1s. per week or 4s. per month. It appears that for cooking purposes electricity is being also largely applied.

Large Rotary Current Plant.—The central electric light station at Chemnitz, which has been carried out for the municipality by Messrs. Siemens and Halske, has been arranged on the high-tension rotary-current system in consequence of the large extent of the district to be served with both light and motive power. It is noteworthy that the station is the largest which has been designed according to this system in Germany. The works, which are situated on the outskirts of the town, contain three fixed triple-expansion condensing engines, made by the Saxon Engineering Works, of Chemnitz. Each engine, when running at 150 revolutions, and with an initial pressure of 165lb., gives from 150 h.p. to 220 h.p. The boilers were constructed by Messrs. Steinmüller, of Gummersbach. Each

Digitized by Google

engine drives a rotary-current dynamo, which is direct coupled, as is also the exciter. At 150 revolutions, and when fully excited, each generator yields 180,000 watts at from 2,000 to 2,200 volts. The current is conveyed to the points of consumption by triple concentric cables, and here it is reduced by transformers to 120 volts. Provision has up to the present been made for 19 transformers of outputs ranging from 10,000 to 50,000 watts. The low-pressure current is again transmitted by triple concentric cables to places outside the inner town, where it is distributed by bare copper conductors. The most distant part to which current is led is about two miles from the central station, but future extensions provide for the transmission of current over a distance of four miles. A special feature of the station is the fact that there has been a large demand for motive power, and of the total output of the generators about one-third is required for this purpose. The working of the rotary current machines is satisfactory, especially in the case of parallel running.

Rating Appeals.—Two important rating appeals were decided on behalf of members of the Machinery Users' Association at the recent quarter sessions. At Chelmsford Messrs. Henry Tate and Sons, who appealed against the assessment of their sugar factory by the West Ham overseers, were represented by Mr. Stevenson-Moore (instructed by Messrs. Dollman and Pritchard, of 39, King street, Cheapside), who informed the court that an arrangement had been come to by which it was agreed the new assessment should be reduced from £9,898 to £7,800. Mr. Montifiore (instructed by Mr. Banes, vestry clerk of West Ham) intimated the consent of his clients to the course, and the rate-book was altered accordingly. Mr. Edward Boyle had been specially retained on behalf of the appellants, and Mr. Balfour Browne, Q.C., on behalf of the respondents, but in view of the compromise which had been arrived at their attendance was not necessary. The witnesses retained for the appellants were Messrs. Humphreys-Davies, S. Green, and R. W. James, M.I.M.E., and for the respondents Messrs. Ryan and R. Hedley. At the Aylesbury sessions the appeal of the Anglo-Swiss Milk Company against the recent reassessment of their factory by the union was heard before Mr. Cripps, Q.C., and a large number of magistrates. Mr. Castle, Q.C., and Mr. Hammond-Chambers were for the respondents, and Mr. E. Boyle and Mr. Stanley Fisher appeared for the appellants. The expert witnesses for the appellants were Mr. Humphreys-Davies, Mr. W. Barnett, and Mr. R. W. James, M.I.M.E., and for the respondents Messrs. Castle and Mason. After a long day's hearing, the chairman decided to adjourn his decision until he had made a view of the premises, which he did on the following morning, and at the opening of the court gave judgment for the appellants, reducing the assessment by £100.

The Telautegraph. — The wires between St. Margaret's and the General Post Office, London, were, a few days ago, used for the purpose of some experiments with the telautograph—the invention of Prof. Gray, of New York, and to which we have referred on previous occasions. The experiments took place between the General Post Office, London, and Cable Hut, St. Margaret's Bay, through which the London and Paris telephone passes. Special instruments were fixed up at both ends, and as this was the first time that long-distance experiments in telautography have taken place in this country, they were watched with unusual interest. The results were good, the messages transmitted being, in every respect, most successful, and the instruments working without the slightest hitch over a distance of 83 miles. Messages were both sent from and received at St. Margaret's Bay. It will be remembered that the principle of the instrument is that it automatically records a *facsimile* of the writing contained in messages. In the experiments on Sunday the receiving pencil recorded with ease and clearness different handwritings, giving thick and thin strokes, dotting i's and crossing t's correctly. In this connection Mr. Armytage Bakewell writes: "It has been stated that the recent experiments in the transmission of autographic messages by electricity between St. Margaret's Bay and London were the first which have been made in this country in long-distance telautography. Will you allow me to point out that this is a mistake, as more than 40 years ago the copying electric telegraph, invented by the late Frederick Collier Bakewell, successfully transmitted autographic messages between Brighton and London. Invisible messages, which could be rendered legible by the recipient, were also transmitted by that system. Great interest was taken by the late Prince Consort in my father's invention, and the inventor had the honour of exhibiting the instruments and of explaining their mechanical and electrical details to His Royal Highness at Buckingham Palace. The copying electric telegraph was subsequently exhibited at the great exhibition of 1851 and received the highest award—viz., the Council medal."

Electric Lighting of Railway Carriages.—An interesting pamphlet on this subject has reached us from the Allgemeine Elektricitäts Gesellschaft (General Electricity Company, of Berlin), who have for several years made a special study of train-lighting, and have carried out exhaustive experiments in this direction on one of the lines of the Prussian State Railways. The company's system differs from that introduced in England in the sense that they recommend the use of storage batteries which, when exhausted, are removed from the train to be recharged, a fresh set of accumulators being in the meantime substituted. Unless otherwise desired, one or more batteries are placed under or in each coach. It is pointed out that in determining the battery pressure, and therefore the number of cells to be used, the loss in pressure through internal resistance of the conductors is comparatively less when high tensions are employed. A battery to supply five 5-c.p. lamps for 40 hours weighs 466lb., with a discharge current at 15 volts, 515lb. at 22·5 volts, and 590lb. at 30 volts. Generally, a pressure of 22·5 volts (12 cells) is recommended, and 30 volts at the highest, although 15 volts is sufficient. If two lamps are to be installed for the lighting of a compartment it is better to provide two batteries, one for energising each lamp. The batteries are placed in a wooden box, either arranged under the floor of the compartment or under the seats of the latter. Connection is made from the battery to the service conductors by means of flexible insulated wires and spring contacts, the wires outside the carriages being protected by gas-piping. A suitable switch is provided for each battery, and this is under the control of the guard or other attendant. The batteries are removed from the train when necessary for recharging at any railway station where a charging-room is available, and fresh ones substituted. The pamphlet recommends two lamps of from 8 c.p. to 10 c.p., or four of from 4 c.p. to 6 c.p. for first and second-class coaches, and two of from 6 c.p to 8 c.p. for third-class compartments. It is mentioned that in the case of the Dortmund-Gronau-Enschede Railway the working results of the electric lighting of the trains have proved that this method is not more expensive than gas illumination, although the service is not very extensive.

The Transvaal.—In our issue of 29th ult., we referred in a note to Messrs. Siemens and Halske's proposal to supply electric power from a central station at Witwatersrand. Commenting on the subject, the *Johannesburg Critic*

Digitized by Google

says: "Whether the scheme of supplying Rand mines with electricity on a large scale will be anything like the success the *Star* so gushingly predicts is at present a matter of opinion. Rand mining companies may take the view that for the sake of a very doubtful saving of a few pounds yearly, it will be a good thing to place themselves at the mercy of a company formed to make profits out of them—and they may think just the contrary, which is the more likely of the two. The fact is, similar schemes to the one in hand have been discussed in a desultory way over the nuts and wine for years, but the first real move to come to business has only just now been taken, and it is rather late in the day. Unfortunately for the eminent Berlin firm, the use of electricity is common on the Rand now, and nearly every company runs its own dynamo and produces its own light, One or two have gone further, and have extensive plants for working as well as lighting purposes. In the former cases the dynamos are run from the large engines, and their running does not make any perceptible difference in the consumption of fuel, so that, although the cost of lighting is worked out in the mine returns, it is really only a book-keeping item. In the latter case the dynamos are run by special engines at a comparatively small cost, and the difference between the cost of production by such a plant, and the cost of production with added profit and allowance for waste in transmission by a central company, cannot be more than a trifling amount which it will not be worth any company's while to save by sacrificing its own plant. A central company may get an opening with the companies which are not so far advanced, as the majority of main reef companies, but it must be prepared to do business on a much bigger scale than the present project involves, and it must also be prepared with up-to-date appliances for the use of the electric fluid as a motive power. No doubt in the future we shall see all the work of a mine performed by electricity, and then a central producing station may do well. Meantime, I wish success to the company, if it goes through, on the ground that it is a step in advance, and does not need a concession to bring it into being."

A New Electric Heater.—An electric heater, which is claimed to mark a distinct advance in this branch of industry, has been devised by Mr. H. Ward Leonard, who has forwarded us the following particulars of the appliance. Mr. Leonard points out that in electrically heated tools the conductor has been hitherto surrounded by a considerable thickness of such fireproof insulation as is a bad conductor of heat, and that therefore the heat is but slowly passed through this bad conductor. The necessity of a resistance which will stand a very high temperature has been such that platinum wire is often used in the construction of such tools, the expense of which is, of course, extremely high, but even this is said to have failed under such conditions. Mr. Leonard has many modifications of the general principles of his heater, but the description of one modification will give a general idea of the invention: the resistance, which is a metal wire, is thinly coated with some form of fireproof insulation, which hermetically seals the conductor from the air—such as enamel or glass. The wall of insulation around the conductor is quite thin. The conductor so insulated is placed in a mould, and a suitable metal is cast about the insulated resistance so as to completely embed it in the cast metal. This surrounding body of metal as it cools subjects the insulated conductor to strong pressure, ensuring perfect mechanical contact throughout. The surrounding metal also hermetically seals the resistance from any possible contact with the air, and from all chemical action. While the insulation surrounding the conductor is of comparatively poor quality as a conductor of heat, the wall of this insulation is so thin that it affords the least possible resistance to the flux of heat from the heated resistance to the surrounding metal body; consequently, the temperature of the heated resistance and the temperature at the surface of use will be as nearly the same as possible, and the resistance is therefore not subjected to a temperature appreciably higher than that of the surface of use. It is claimed to be possible to operate tools heated on this system at a bright red heat without any destructive effect whatever. The Carpenter Enamel Rheostat Company, of which Mr. Leonard is president, will manufacture apparatus under this patent. Among the various kinds of apparatus in which this system will be embodied are soldering and embossing irons, flat-irons, and tailors' gooses, cooking utensils, electric stoves, ovens, egg-boilers, etc.

The Thermogen.—In writing of the last Royal Society conversazione, the *Lancet* mentioned as an exhibit of particular interest to the medical man an invention by Mr. C. T. Snedekor for heating by electricity a quilt or cushion. It was obvious that such a quilt could be used in private or in hospital for many therapeutic purposes. This quilt, which he named the thermogen, the *Lancet* has since had an opportunity of putting to practical trial under more lengthened observation, and has no hesitation in reporting upon it thoroughly favourably as an appliance that might be of great value in all hospitals, or, for that matter, in all private houses where an electric main is handy. The quilt contains a coil of wire consisting of a special alloy of known composition and electrical resistance, and bent in the fashion of a gridiron. The coil is enclosed in suitable insulating and non-conducting material, the whole being embedded in cotton-wool or other soft substance provided with a silk or woollen covering. The resistance offered by the coil to the flow of the current—the friction set up, so to speak, by the passage of the current through the wire—produces the heat, in accordance with the laws of Ohm and Joule, in the same way that heat, and eventually light, are produced in the filament of the electric incandescent lamp when a current is forced through it. The coil contained in the quilt which was examined is constructed to admit of connecting with the terminals of an ordinary installation supply of 100 volts pressure, which effects a uniform temperature in the quilt of about 150deg. F. In the event, however, of the temperature rising beyond that point, which would be the case if there were an increase of pressure in the electric mains, a safeguard is provided in the end of the coil in the form of a "fuse," which would instantly melt and so automatically shut off the current. The quilt may be readily attached to wall plugs, pendants, or still more conveniently to table lamp terminals. In places where the electric current is not supplied for lighting purposes an accumulator may be substituted with equally satisfactory results. The direction in which such an invention might be medically useful is first, and our contemporary thinks in chief, on the operating table. In lengthened operations, or in those necessarily attended with much hæmorrhage, where artificial means to sustain the patient's temperature are required, most surgeons can recollect cases when the blankets and hot water at present in vogue have proved a decided nuisance. In such cases this quilt would be found literally invaluable as a soft, dry, warm, and convenient covering. Again, in cases of chronic rheumatism or of that undefined neuralgia generally called lumbago the quilt might prove comforting. Also, in cases of senile slowness of circulation attended with general chilliness such an appliance would be very useful. The thermogen is receiving trial at several of our largest hospitals.

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 35.)

§ 37. All electrical quantities can be expressed in terms of the mechanical or chemical or thermal effects produced by electricity. Chemical and thermal effects are, however, measured in terms of some mechanical unit, so that it is only necessary to attend to the relations between the electrical quantities and the mechanical units. We may start (*a*) from the experimental results of Coulomb, by defining the force between two quantities of static electricity, or the force between two quantities of magnetism; (*b*) from Ampère's formula by defining the force between two elements of currents of electricity. We thus arrive at what is commonly called the *electrostatic* units, the *electromagnetic* units, and the *electrodynamic* units. It shall be shown subsequently that by giving a certain value to the constant in Ampère's formula, the electrodynamic unit current is equal to the electromagnetic unit current.

§ 38. The clearest statement of the relations between the electric quantities of which I know is given in a report by Clerk Maxwell to British Association meeting at Newcastle-on-Tyne, 1863, and reprinted with various other reports by Spon, London, 1873. I quote from the second report, the members of the committee being Prof. Wheatstone, F.R.S., Prof. Williamson, F.R.S., Mr. C. F. Varley, Prof. Thomson, F.R.S., Mr. Balfour Stewart, F.R.S., Mr. C. W. Siemens, F.R.S., Dr. A. Matthiessen, F.R.S., Prof. Maxwell, F.R.S., Prof. Miller, F.R.S., Dr. Joule, F.R.S., Mr. Fleeming Jenkin, F.R.S., Dr. Esselbach, Sir C. Bright:

"... The electrical phenomena susceptible of measurement are four in number—current, E.M.F., resistance, and quantity. ... Their relations one to another are extremely simple, and may be expressed by two equations.

"First by Ohm's law, experimentally determined, we have the equation

$$C = E/R \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where C = current, E = E.M.F., and R = resistance. From this formula it follows that the unit E.M.F. must produce the unit current in a circuit of unit resistance; for if units were chosen bearing any other relation to each other, C would be equal to x E/R, where x would be a useless and absurd factor, complicating all calculation, and confusing the very simple conception of the relation established by Ohm's law.

"Secondly, it has been experimentally proved by Dr. Faraday that the statical quantity of electricity conveyed by any given current is simply proportional to the strength of the current, whether electromagnetically or electro-chemically measured, and to the time during which it flows; hence, in mathematical language, we have the equation

$$Q = C\,t \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where t = time, and Q = quantity. From this equation it follows that the unit of quantity must be the quantity conveyed by the unit current in the unit of time; otherwise we should have $Q = y\,C\,t$, where y would be a second useless and absurd coefficient. From equations (1) and (2) it follows that only two of the electrical units could be arbitrarily chosen, even if the natural relation between electrical and mechanical measurements were disregarded. Thus, if the E.M.F. of a Daniell's cell were taken as the unit of E.M.F., and the resistance of a metre of mercury of one square millimetre section at 0deg. C. were taken as the unit of resistance, it would follow from equations (1) and (2) that the unit of current must be that which would be produced by the Daniell cell in a circuit of the above resistance, and the unit of quantity would be the quantity conveyed by that current in a second of time. Such a system would be coherent; and if all mechanical, chemical, and thermal effects produced by electricity could be neglected, such a system might perhaps be called absolute. But all our knowledge of electricity is derived from the mechanical, chemical, and thermal effects which it produces, and these effects cannot be ignored in a true absolute system. Chemical and thermal effects are, however, now all measured by reference to the mechanical unit of work; and, therefore, in forming a coherent electrical system, the chemical and thermal effects may be neglected, and it is only necessary to attend to the connection between electrical magnitudes and the mechanical units. What, then, are the mechanical effects observed in connection with electricity? First, it has been proved that whenever a current flows through any circuit it performs work—or produces heat or chemical action equivalent to work. This work or its equivalent was experimentally proved by Dr. Joule to be directly proportional to the square of the current, to the time during which it acts, and to the resistance of the circuit; and it depends on these magnitudes only. In mathematical language this is expressed by the equation

$$W = C^2\,R\,t \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Where W = the work equivalent to all the effects produced in the circuit, and the other letters retain their previous signification. This is the third fundamental equation affecting the four electrical quantities, and represents the most important connection between them and the mechanical units. From equation (3) it follows (unless another absurd coefficient be introduced) that the unit current flowing for a unit of time through a circuit of unit resistance will perform a unit of work or its equivalent. If every relation existing between electrical and mechanical measurements were expressed by the three fundamental equations now given, they would still leave the series of units undefined, and one unit might be arbitrarily chosen from which the three other units would be deduced by the three equations; but these three equations by no means exhaust the natural relations between mechanical and electrical measurements. For instance, it is observed that two equal and similar quantities of electricity collected in two points repel one another with a force, F, directly proportional to the quantity, Q, and inversely to the square of the distance, d, between the points. This gives the equation

$$F = Q^2/d^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

From which it would follow that the unit quantity should be that which at a unit distance repels a similar and equal quantity with equal force. The four equations now given are sufficient to measure all electrical phenomena by reference to time, mass, and space only, or in other words, to determine the four electrical units by reference to mechanical units. Equation (4) at once determines the unit of quantity, which by equation (2) determines the unit current; the unit of resistance is then determined by equation (3), and the unit E.M.F. by equation (1). Here, then, is one absolute or coherent system, starting from an effect produced by electricity when at rest. The units based on these four equations are precisely those called by Weber electrostatical units, although, it may be observed that he chose those units without reference to what is here called the third fundamental equation, or, in other words, without reference to the idea of work, introduced into the system by Thomson and Helmholtz.

"The four equations are sufficient to determine the four units, and into this system no new relation can be introduced. The first three equations may, however, be retained, and a distinct absolute system established by substituting some other relation between electrical and mechanical magnitude than is expressed in equation (4); and, indeed, the electrostatical system just defined is not that which will be found most generally useful. It is based on a statical phenomenon, whereas at present the chief applications of electricity are dynamic, depending on electricity in motion, or on voltaic currents with their accompanying electromagnetic effects. Now, the force exerted on the pole of a magnet by a current in its neighbourhood is a purely mechanical phenomenon. This force (f) is proportional to the magnetic strength (m) of the pole of the magnet, and to the strength of the current, C; and if the conductor be at all points equidistant from the pole, or, in other words, be bent in a circle of the radius, k, round the pole, the force is proportional to the length of the conductor (L); it is also inversely proportional to the square of the distance (k) of the pole from the conductor, and is affected by no other circumstances than those named. Hence we have

$$f = C\,L\,m/k^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Digitized by Google

From this equation it follows that the unit length of the current must produce the unit force on a unit pole at the unit distance. If the equations (1), (2), (3), and (5) are adopted as fundamental, they give a distinct absolute system of units, called by Weber the electromagnetic units. Equations (4) and (5) are incompatible one with another, if equation (2) be considered fundamental; but the electromagnetic units have a constant and natural relation to the electrostatic units. It will be seen that in the fundamental equation (5) of the electromagnetic system, besides the measurement of time, space, and mass, alone entering into the other equations, a fourth measurement (m) of a magnetic pole is required; but this measurement is in itself made in terms of the mechanical units, for the unit pole is simply that which repels another equal pole at unit distance with unit force. Thus in the electromagnetic, as in the electrostatic system, all measurements are ultimately referred to the fundamental units of time, space, and mass. The electromagnetic units are found much the more convenient when dealing, as we have now chiefly occasion to do, with electromagnetic phenomena.

"The relations of the electromagnetic units one to another and to the mechanical units may be summed up as follows: The unit current conveys a unit quantity of electricity through the circuit in a unit of time. The unit current in a conductor of unit resistance produces an effect equivalent to the unit of work in the unit of time. The unit current will be produced in circuit of unit resistance by the unit E M.F. The unit current flowing through a conductor of unit length will exert the unit force on a unit pole at unit distance. (In the electrostatic system, all the above propositions hold good except the last, for which the following must be substituted: The unit quantity of electricity will repel a similar quantity at the unit distance with unit force)."

Electrostatic System of Units.

§ 39. Coulomb, experimenting with his torsion balance, found that the force of repulsion between similar quantities of electricity varied inversely as the square of the distance between them, and directly as the product of the two quantities of electricity. In symbols, if q, q^1 be the two quantities of electricity, and r the distance between them, then $F \propto \frac{q\,q^1}{r^2} = \text{constant} \times \frac{q\,q^1}{r^2}$.

Faraday proved that different substances have different powers of transmitting electric disturbances, so that the force of repulsion between two similar quantities of electricity depends not only on the quantities and on their distance apart, but also on the intervening medium. Let us denote this power of transmitting electric disturbances, or the specific inductive capacity of the medium by K, then $F = \text{constant} \times \frac{q\,q^1}{K\,r^2}$.

It is thus necessary to fix on some standard medium for defining the electrostatic quantity of electricity. In the ordinary electrostatic system the standard medium is air, at temperature 0deg. C., and at standard atmospheric pressure. The constant in the equation will be unity if we define unit quantity of electricity as that quantity which, concentrated at a point* one centimetre from an equal and similar quantity also concentrated at a point, would repel it with a force of one dyne, when the medium across which the electric action is transmitted is air. The dimensional formula for unit *quantity* of electrostatic electricity is therefore

$$[q] = [F \,.\, K \,.\, L^2]^{1/2};$$
$$= [L\,M\,T^{-2} \,.\, K \,.\, L^2]^{1/2};$$
$$= [L^{3/2}\,M^{\frac{1}{2}}\,T^{-1}\,K^{1/2}].$$

In the ordinary electrostatic system of units, K for air is supposed to be of zero dimensions, but Prof. Rücker, in a paper entitled "Suppressed Dimensions of Physical Quantities,"† advocates the retaining in the tables of dimensions the symbols K and μ (inductive capacity and magnetic permeability), and speaks of these as secondary fundamental units. The dimensions of K and μ are thus supposed to be undetermined, and the ordinary electrostatic and electromagnetic systems can be derived from what follows by deleting K and μ respectively.

Oliver Heaviside* advocates, for no valid reason, that the constant in the above equation should be $\frac{1}{4\pi}$, so that $q^2 = 4\pi\,K\,L^2\,F$, and hence deduces what he terms rational units.

§ 40. Electric *surface density*, σ, of a conductor at any point is measured by the number of units of electricity per unit of area. Hence its dimensional formula is

$$[\sigma] = [q\,L^{-2}] = [L^{-\frac{1}{2}}\,M^{\frac{1}{2}}\,T^{-1}\,K^{\frac{1}{2}}].$$

§ 41. The unit of *current*, γ, in a conducting wire is the current in which the unit quantity passes in the unit of time. Hence its dimensional formula is

$$[\gamma] = [q\,T^{-1}] = [L^{\frac{3}{2}}\,M^{\frac{1}{2}}\,T^{-2}\,K^{\frac{1}{2}}].$$

§ 42. The *intensity of an electric field* at a point, f, or the electric force at any point in an electric field, is the force with which a unit of electricity would be acted on if placed at that point. The force, F, on a quantity of electricity, q, in a field of electric force of intensity, f, is $F = f\,q$. Therefore the dimensional formula for the electric force at a point is

$$[f] = [F\,q^{-1}];$$
$$= [L\,M\,T^{-2} \times L^{-\frac{3}{2}}\,M^{-\frac{1}{2}}\,T\,K^{-\frac{1}{2}}];$$
$$= [L^{-\frac{1}{2}}\,M^{\frac{1}{2}}\,T^{-1}\,K^{-\frac{1}{2}}].$$

§ 43. Unit *difference of electric potential*, v, exists between two points in an electric field when unit work is done in carrying unit quantity of electricity from the one point to the other against the electric forces. Hence if q units of electricity is carried through a difference of electric potential expressed by v, the work done $W = q\,v$. Therefore the dimensional expression for difference of electric potential is

$$[v] = [W \,.\, q^{-1}];$$
$$= [L^2\,M\,T^{-2} \times L^{-\frac{3}{2}}\,M^{-\frac{1}{2}}\,T\,K^{-\frac{1}{2}}];$$
$$= [L^{\frac{1}{2}}\,M^{\frac{1}{2}}\,T^{-1}\,K^{-\frac{1}{2}}].$$

Electric potential at a point due to a quantity, q, of electricity is the quotient obtained by dividing the quantity of electricity by the distance and by the inductive capacity. Thus $[v] = [q\,L^{-1}\,K^{-1}] = [L^{\frac{1}{2}}\,M^{\frac{1}{2}}\,T^{-1}\,K^{-\frac{1}{2}}]$.

§ 44. The *capacity* of a conductor, c, is the quotient obtained by dividing the quantity of electricity with which it is charged by the potential which this charge produces in it. Hence its dimensional formula is

$$[c] = [q\,v^{-1}] = [L^{\frac{3}{2}}\,M^{\frac{1}{2}}\,T^{-1}\,K^{\frac{1}{2}} \times L^{-\frac{1}{2}}\,M^{-\frac{1}{2}}\,T\,K^{\frac{1}{2}}] = [L\,K].$$

Hence, if, as in the ordinary electrostatic system, we suppose $[K] = 1$, then the dimensions of capacity will be that of length, and is correctly expressed as so many centimetres.

§ 45. The *resistance* of a conductor, r, is by Ohm's law measured by the difference of potential at its extremities divided by the current produced in it thereby. Therefore its dimensional formula is

$$[r] = [v\,\gamma^{-1}] = [L^{\frac{1}{2}}\,M^{\frac{1}{2}}\,T^{-1}\,K^{-\frac{1}{2}} \times L^{-\frac{3}{2}}\,M^{-\frac{1}{2}}\,T^2\,K^{-\frac{1}{2}}$$
$$= [L^{-1}\,T\,K^{-1}].$$

The resistance of a conductor is also measured by the time a unit of electricity requires to pass through it when unit difference of potential is maintained between its ends. Hence $[r] = [v\,.\,T\,.\,q^{-1}] = [L^{-1}\,T\,K^{-1}]$.

§ 46. *Conductance* is the reciprocal of resistance, and its dimensional expression is therefore

$$[L\,T^{-1}\,K].$$

* Of course it is physically impossible to concentrate a quantity of electricity at a point; but a practical problem can be stated similar to that in footnote to § 11.

† *Proceedings* of the Physical Society, vol. x., 1888-90.

* "Electromagnetic Theory," by Oliver Heaviside, pp. 117 to 127.

§ 47. These electrostatic quantities may now be put into a tabulated form for convenience of reference.

Name.	Symbol.	Relation to other quantities.	Dimensions in L M T K.
Quantity ...	q	$\sqrt{\text{force} \times (\text{distance})^2 \times K}$	$L^{3/2}M^{1/2}T^{-1}K^{1/2}$
Surface density ..... Electric displacement...	σ	quantity ÷ area	$L^{-\frac{1}{2}}M^{\frac{1}{2}}T^{-1}K^{\frac{1}{2}}$
Current	γ	quantity ÷ time	$L^{\frac{3}{2}}M^{\frac{1}{2}}T^{-2}K^{\frac{1}{2}}$
Intensity of electric field	f	force ÷ quantity	$L^{-\frac{1}{2}}M^{\frac{1}{2}}T^{-1}K^{-\frac{1}{2}}$
Potential ...	v	work ÷ quantity / quantity ÷ distance	$L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-1}K^{-\frac{1}{2}}$
Capacity ...	c	quantity ÷ potential	$L\ K$
Resistance ...	r	potential ÷ current	$L^{-1}T\ K^{-1}$
Conductance.	$1/r$	—	$L\ T^{-1}\ K$

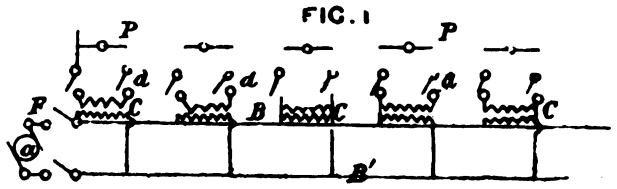
(To be continued.)

DISTRIBUTION OF ELECTRICAL ENERGY BY ALTERNATING CURRENTS.

We have received the following description of Mr. W. Lowrie's intraposed automatic system of electrical distribution:

Experience has shown, and it has come to be generally admitted that the present methods of distributing electric energy over large areas and of safeguarding the circuits are open to great improvement. After years of patient work and the trial of many systems of distribution only two now practically hold the field. The simple parallel or low-tension system, at once the most simple and safe, is unfortunately limited to a very small area of supply. A modification of the low tension called the three-wire system (which is in reality a series parallel system), has been extensively used with a view to increase the low-tension area of supply. The application of this and other cognate systems must, however, inevitably grow less and less as the use of electricity becomes more general throughout the country and the densely populated quarters of large towns or districts are supplied with it. The public opposition to the erection of electric lighting stations in crowded areas has already been so great that any attempt to sufficiently increase their number in order to cope with anticipated public requirements is sure to be stoutly resisted, and the time is not far distant when they will no longer be tolerated in such places as we now see them.

FIG. 1.

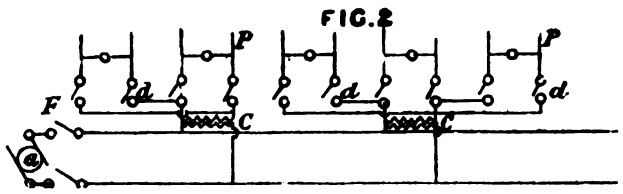


The enormously increasing difficulties met with in all endeavours to extend the low-tension system to meet the demands over even moderate areas of supply have driven electrical engineers, in order to obtain economy, commercial efficiency, and comply with the Board of Trade requirements, to adopt the high-tension system of distribution with transformers, to reduce the pressure to the limits imposed by it and the requirements of translating devices. A short *résumé* of the progress of the high-tension system taking it step by step, and illustrating these steps by diagrams showing how it gradually advanced to the position now claimed for it by its supporters, will help to a better understanding of them and a just appraisement of their value.

When the high-tension parallel system was first installed, a pair of high-tension mains were laid throughout the area of supply, and converters connected in parallel were placed on the premises to be lighted, and secondary mains installed for the low-tension supply to the lamps taking current direct from the converters, as shown in Fig. 1.

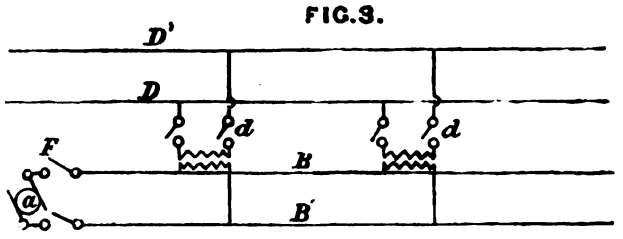
It was, however, soon found that when small installations and many of them were connected to the circuit each with its own small converter, the magnetising current at the time of light loads was nullifying the advantages gained by the use of high tension. It was in consequence changed in many places to the form described in Fig. 2, which shows several premises served from one large con-

FIG. 2.



verter fixed in one of them; in other words, more than one house was dependent on one transformer. This led to connecting the transformers together by pairs of compensating or secondary mains, and connecting the house circuits (not shown) to these mains, instead of direct from the converters, as shown in Fig. 3, thus making every house dependent on more than one transformer, and converting the system into a compound system of high and low tension. This, although a great step forward towards the solution of the electrical distribution problem, did not do away with

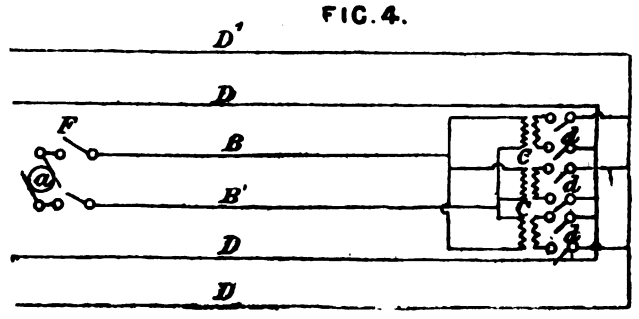
FIG. 3.



the many serious difficulties encountered when transformers were working in parallel, or the magnetising current losses, or enable transformer or high-tension connections to be made without stopping the supply over the whole circuit, or the great danger run by the operatives while testing or repairing it.

This led to the sub-station system (Fig. 4), which consists of a high-tension supply to a number of converters, placed in a suitable building, and a low-tension system diverging from these converters. Any converter could be cut out by hand, thus saving the magnetising current; but

FIG. 4.



the same laws that condemn the simple low-tension supply apply equally here, and the cost of the low-tension system from the sub-station is found to be prohibitive except in very densely populated towns or districts, and recourse has here again been had to the three-wire system.

A further development consists of a system sufficiently illustrated by Fig. 3, but here the converters are either in the roadway or in elevated street-boxes, or on walls of houses, so that an attendant is required to go round and turn off both high and low tension from the converters. This is manifestly both a dangerous, expensive, and unreliable method, so that it has been suggested to switch the primary at the central station. This control of the primary supply over the area brought with it the necessity of controlling the secondary windings of the converters so that they could be severed from the secondary or distributing

Digitized by Google

system, to which all converters are connected in parallel. It has been proposed to accomplish this by hand-worked switches at the converters; this is not practicable where immediate control is required to meet the exigency of a variable demand. It has also been proposed to accomplish the same object by separate control wires run from the central station to each converter, but the obvious expense, complication, and difficulties of such a system will prevent this method being used. Added to the disadvantages just referred to, none of the systems mentioned provide against a most serious danger to all electrical machinery working in parallel, either alternators or converters—that is, the risk in case of the failure of any machine on the circuit, that the failing machine will cut out the fuses of the sound machines instead of its own, and thus break down the whole system; nor yet do they make provision for immediately reconnecting the failing machine if it should be restored. Further, in case of any hand-worked switch being inadvertently left on, the primary main, although switched off at the station, would remain charged at full pressure by the back action from the secondary mains through the converter so left on. The same danger occurs in mains working in parallel, as should two mains of different signs make accidental earth at one time they would form a short circuit and blow out the fuses of both circuits.

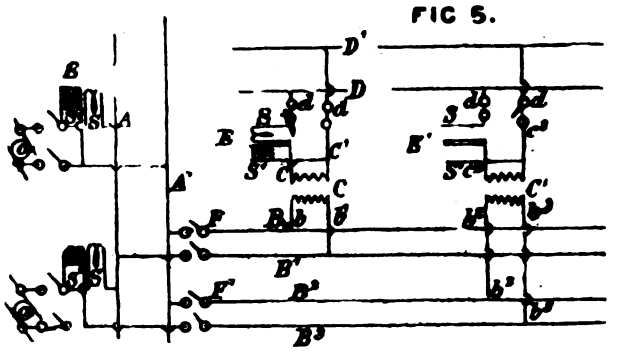
The latest of these developments is the compound intraposed automatic system recently designed by Mr. W. Lowrie. It is claimed that Lowrie's compound intraposed automatic system completely removes the foregoing and all other difficulties hitherto met with, and obtains both safety, economy, and easy control of electric current circuits, where two or more units of supply apparatus are worked in parallel, as in the examples following:

(*a*) Two or more primary generators working in parallel, directly supplying a distributing system of mains. (*b*) Two or more primary generators, working in parallel, supplying a transformer or group thereof; (*c*) two or more primary generators, working in parallel, supplying two or more transformers, whose secondary windings are connected in parallel to a distributing system of mains; (*d*) two or more feeder mains, each supplied from a separate source, feeding in parallel a distributing system of mains; (*e*) two or more feeder mains, supplied from a common source, feeding in parallel a distributing system of mains; (*f*) two or more feeder mains, supplied from a common source, feeding the primary circuits of transformers; (*g*) two or more feeder mains, each supplied from a separate source, feeding transformers which are arranged in parallel to supply a distributing system of mains; (*h*) two or more transformers arranged in parallel to supply a distributing system of mains.

By the accompanying drawings it will be seen that Mr. Lowrie, in his compound intraposed parallel system of electrical distribution, places converters at intervals on the lines of mains covering the area to be supplied buried in the road, or in chambers in the roads, or on the premises to be supplied (or some of them), and connects the primary winding of the converters alternately to two or more separate pairs of mains or conductors coming direct from the switchboard at the generating station, or other suitable place, as shown in Figs. 5 and 6. The converters being so arranged on the said sub-divided primary mains (the aggregate of such mains as to sectional area of copper being only equal to that of a single pair) that a converter or group of converters, or a number of converters or groups of converters at intervals along the line of mains can be cut out by suitable switching apparatus at the central or other station, and the converters separated from the secondary supply mains by an automatic controller switch placed in circuit with each converter or group thereof, the action of the controller being called into play by the act of making or breaking the primary circuits of the converters to which they are attached, whether the same be purposely or accidentally done. It is proposed to place controllers near each alternator to protect them and the system in case their pressure should fall below the required voltage.

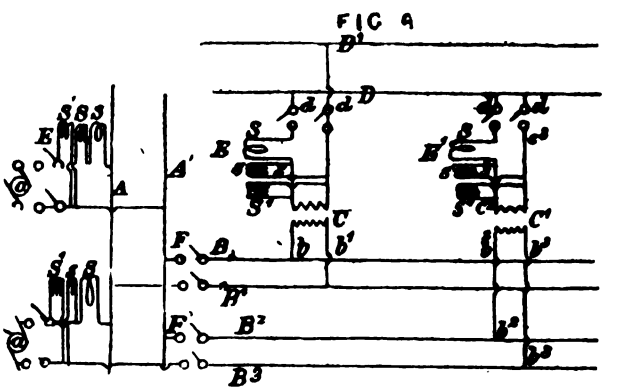
Figs. 7 and 8 are diagrams of one form of Lowrie's automatic controller switch, with electric connections thereto, adapted for use with alternating or interrupted currents, the difference between them consisting mainly of an extra shunt winding in Fig. 8, which may also be used with continuous currents. Figs. 5 and 6 are also diagrams indicating the relative positions of the said switches in a sub divided system of mains for the distribution of electrical energy, Fig. 5 being adapted for alternating currents only.

FIG 5.



In these diagrams, A A^1 indicate the omnibus bars, or their equivalents, in a station fed by generators, *a* a^1. Two or more separate mains, B B^1 and B^2 B^3, are connected directly to the bars, A A^1, at the station, and thence are connected alternately to the primary windings, *b* b^1 and b^2 b^3, of two or more transformers or converters, C and C^1. The secondary windings, *c* c^1 and c^2 c^3, of the said transformers are connected to the distributing system of mains, D D^1, which connect together the secondary terminals, *d d*, of the transformers, and all the supply or lamp wires are joined to the distributing mains, D D^1.

FIG 6



When the primary circuit, B, for example, is put in action at the station, by hand at F, or otherwise, the automatic switch, E, operates to put the secondary terminals, *d d*, of the transformer, C, in connection with the distributing mains, D D^1, and consequently with all the supply wires joined thereto. If the load increases the second converter shown, C^1, is similarly put into action at the station by joining up the primary circuit, B^2 B^3, with the bars A A^1, and the same method is employed with any other converters, similarly arranged, that may be on the circuit D D^1. Each converter, C, shown on the drawings

FIG. 8.

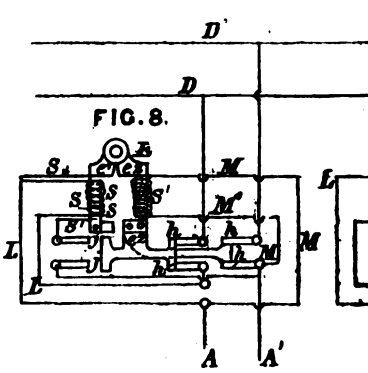


FIG. 7.

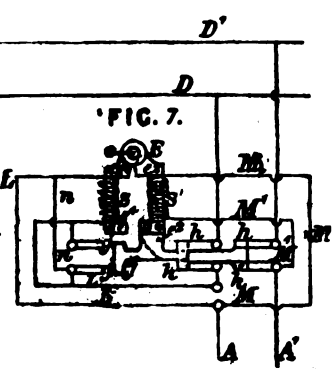

is intended to represent either a single converter or a group of converters fed by a separate primary main or conductor, whatever may be the number of converters in the group. These converters, or groups of converters, may be added along the same line of mains at intervals indefinitely,

Digitized by Google

and these primary feed mains, B B^1, may be laid close to, though insulated from, each other, so that the primary current may be operating in one pair of conductors, and not in another pair adjoining thereto or they may have a common return.

In the diagram, Fig. 7, of the automatic controller switch, E, an electromagnet is shown having two limbs pivoted together at *e*, one limb, e^1, being rigidly fixed, the other limb, e^2, being pivotally movable on the joint *e*. Polar projections are formed in any convenient manner, and the core is laminated. The movable limb, e^2, carries four contact-pieces, *h* (suitably connected to the secondary circuit, *c* c^1, of the converter, E, as in Figs. 5 and 6 for example), operating simultaneously in one direction, and two contacts, *j*, operating simultaneously in the opposite direction. These are so arranged that when the contact-pieces, *h*, are in circuit, the contact-pieces, *j*, are out of circuit; and conversely when the latter are in circuit, the connection is broken at all four of the, *h*, contacts. The several, *h*, contacts each form a pole switch on the mains, of the shunt coil, S^1, upon the series coil, S, which is in series with the feeder mains, A A^1, from which it will be seen that the electromagnet, E, acts as an auxiliary transformer. The series and shunt coils, S and S^1, are adapted to produce poles of the like name, and when this occurs the movable limb, e^2, is repelled, the contacts, *h*, are made, and the short-circuit contacts, *j*, are broken, as shown in the drawings, Figs. 7 and 8. When the current potential falls in the feeder mains, A A^1, from any cause, and so fails to maintain its power to feed the distributing mains, D D^1, then the direction of the current through the series coil, S, will be reversed (through the higher back E.M.F. from the mains, D D^1, fed by other sources in parallel), while the direction of current in the shunt coil, S^1, would remain the same—thus bringing about unlike poles of the limbs, e^1 e^2, with mutual attraction, which, breaking all the contacts, *h*, in one direction would make the *j* contacts in the opposite direction, and short-circuiting the series coil, *s*, through the circuit, *n n*, the feeder mains, A A^1, and both series and shunt coils, S and S^1, are rendered dormant.

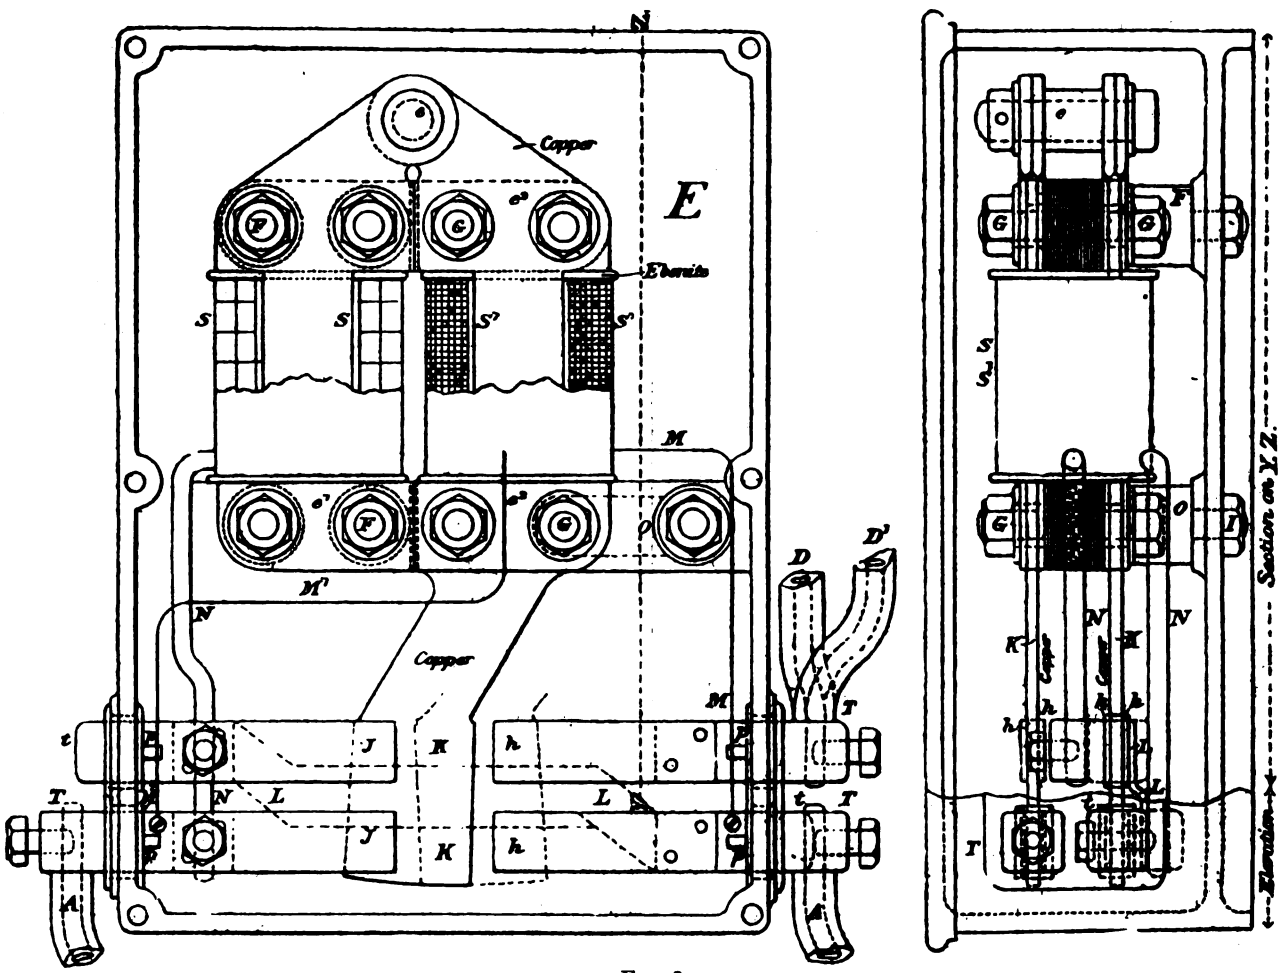

FIG. 9.

and all the parts are suitably insulated, as well understood by electricians. The other two contact pieces, *j*, when in circuit, form a short circuit for a series coil, S, through the circuit, *n n*, in Fig. 7, and connect a cross-wound shunt, in Fig. 7.

In these controller switch diagrams, Figs. 7 and 8, the mains, A A^1, are to be taken as feeder mains to the controller, whether supplied from a primary or secondary source, and D D^1 the distributing mains, fed by two or more sources (primary or secondary) of electrical energy. The series coil, S, is connected by the circuit L L to work in series with the main circuit, A A^1, while the shunt coil, S^1, is placed across the circuit by the conductors, M M^1. The action of the switch, as shown in Fig. 7, is as follows: The circuit is closed on the right-hand side at all the, *h*, contacts, the feeder mains, A A^1, being in action on the distributing mains, D D^1. The current in the feeder mains, A A^1, is designedly a little lower in E.M.F. than that in the circuit D D_1, but the voltage is increased to that in the circuit D D^1 (after passing the switch) by the action

When the current is again switched on—or the necessary potential maintained—in the feeder mains, A A^1, the shunt coil, s^1, is at once put into action through the circuit, M M^1, but it could not act on the series coil, S, if it were not for the short-circuit contact, *j*, as the said coil would be on open circuit. The short circuit, therefore, will admit of a strong current being induced in the coil, S, which, producing like polarity in the limb e^1 to that of e^2, repels the latter or movable limb—thus making good all the *h* contacts, and breaking that of the short circuit, *j*, makes all the circuits good for feeding the distributing mains, D D^1.

Fig. 8 is a diagram of an automatic switch and its connections adapted for working with either alternating or continuous currents. The arrangement is similar to that of Fig. 1, and the description of the latter will apply likewise to Fig. 2, with the exception that the short circuit upon the series coil, S, by the line *n n* is omitted and replaced by the shunt coil, *s*, wound on the same limb, e^1, as the series coil, S; while its circuit (the circuit of *s*) is made or broken at *j*. The connections are so made when

Digitized by Google

using continuous currents that when the mains, A A^1, are put into action, the two shunt coils, S^1 and *s*, by producing like poles, repel each other, and so make good the circuit through the contacts, *h*, and series coil, S, while at the same time the second shunt coil circuit is broken. On the other hand, on the cessation or reduction (to any required degree) of potential energy in the feed mains, A A^1, a reversal of current takes place in the series coil, S, thus bringing about unlike poles of the limbs e^1 e^2, with mutual attraction, consequently breaking the *h* contacts, and making the *j* contacts as before.

Fig. 9 is a drawing of a 200 ampere controller for use with transformers, the reference letters remaining the same as in the foregoing, with the following additions: K, connecting pieces of hard copper; O, stop and guide for moving arm; T, terminals for cable connection; *t*, dummy terminals to carry contact pieces, *h*, where T are not required; D and D^1 are cables leading thereto. It is to be noted that solenoids only may be employed instead of the electromagnet described; and that the limbs or coils referred to may be reversely arranged, or even both limbs movable or any other mechanical arrangement may be used embodying the electrical principle entailed without departing from the nature of this invention. The advantages claimed for the Lowrie compound intraposed automatic system are as follows:

(1) It will save largely the costs of installing, as it will in all cases permit the use of the copper in the mains to its fullest carrying capacity over very extended areas, for although subdivided and possessing, therefore, all the advantages of duplication the aggregate of such mains as to sectional area of copper will not exceed that of a single pair. (2) It will reduce loss in transmission in the mains to a minimum and prevent variation of pressure due to varying load without regulation on the circuits, while additions to the number of primary mains can be made from time to time, thus increasing its aggregate section and increasing thereby the capacity of the low-tension distributing mains without increasing their section by the interposition of additional converters at suitable points fed by such additional primary mains. (3) It will save cost of working, as only sufficient converters and dynamos actually required to do the work on the circuits need be in action, thus avoiding the consumption of energy by friction and useless magnetising current. (4) It will permit the regulation and control of the whole system from the central station, and the act of breaking or making any primary circuit will disconnect or connect the secondary windings of the converters thereon from the general low-tension supply system without interrupting the supply to any consumer. (5) It will ensure in case of any dynamo or transformer breaking down that the faulty machine is automatically cut out and not the sound machine as at present when two or more are working in parallel, and also automatically replace it if the fault is only temporary and removed. (6) It will prevent any dynamo or transformer being reversed or fed by the others when working in parallel should its E.M.F. fail from any cause. The automatic controller will act as a non-return valve, and will cut out any machine not doing its duty, and restore it if the cause is only temporary and removed. (7) It will not consume energy in the automatic control switches when the machines are either in or out of action. (8) It will be absolutely reliable, as the automatic switch may be made to any power desired, as the energy is only used at the moment of making or breaking. (9) It will not rely on an instantaneous rush of current, as the power in the control switch will remain in action until the duty of the switch has been performed, then will instantly cease. (10) It will entirely remove serious risks from the accidental earthing of any two mains of opposite polarity when two or more pairs are working in parallel from common omnibus bars or through transformers—the most faulty will be automatically cut out, and if necessary be immediately reinstated by a cross-switch making the faulty mains of same sign, the exciting circuits of alternators breaking down, or accident to any part of any machine interfering with the constant supply to consumers. (11) It will permit repairs, additions, testing, etc., to be done at any time without danger to the operatives or interference with the constant supply to any consumer, as any section of the subdivided main may be cut out of action for any such purpose without the remainder being affected thereby. (12) It will not require any disturbance of the roads when once the culverts are installed, as by this method of sub-division all the mains, both of high and low tension, even for very dense districts, will be of small section, flexible, and therefore easily handled, drawn-in, added to up to the capacity of the culverts, and all joints made from the surface. (13) It is easily applied to existing systems, and will greatly increase their capacity, safety, reliability of supply, and decrease their cost of working.

If, therefore, due consideration be given to the above advantages, and the fact be recognised that the loss in mains on any parallel circuit must, for the sake of the regulation of the pressure, be only a small percentage of the total E.M.F. of the circuits, the unsuitability of the low-tension as compared with the compound intraposed automatic system for distributing electricity over even moderately large areas will be at once apparent, and in this relation the following law should be strictly borne in mind—viz., that in an electrical circuit distributing equally along its length, the loss in the mains is as the square of length; or, the mains must be increased in like proportion; when, the carrying capacity of the copper could only be utilised inversely as the square.

The writer of the foregoing in comparing the value to be attached to the system described, had recourse to the Board of Trade returns for 1893, and the annexed is a summary of a *pro forma* balance-sheet of average of 29 central stations which will be interesting:

Electricity Supply Only (High, Extra High, and Low Tensions), 29 Stations Averages.

Cr. (1893.)		
15,500,000 units at 5·9		£381,000
Average price received	5·90	
Average price cost	3·78	
Average price margin P. and D.	2·12	
Per cent. cost to revenue	64·55	
Per cent. cost to capital	5·49	
Per cent. revenue to capital	8·50	
Per cent. on capital for redemption	3·33	
Per cent. on capital for deficit	0 32	
Units to the £ capital	1·00	
Dr. Costs.		
Per cent. to capital.		
2·58 costs low tension		£116,000
2·17 costs high tension		96,450
0·74 costs extra high tension		33,540
5·49		£245,990
Say		£246,000
3 33 redemption fund at 3·33 per cent.		149,400
8·82 on £4,482,000		£395,400
·32 deficit.		
8·5 0·32 per cent. deficit		14,400
		£381,000

If redemption fund is reduced to 3 per cent. accounts will balance without deficit.

PHOTOMETRY*

BY CAPTAIN W. DE W. ABNEY, C.B., F.R.S.

What I have undertaken in these lectures is to endeavour to give an idea of the general principles of photometry, almost restricting myself to the scientific aspect of the question. Photometry, in its broadest sense, is the measurement of light, at least, so we must think, from its derivation. Now, the light measured may be light coming from an object, or from a self-luminous body, such as a candle or the sun, or it may be the light transmitted through objects. In the second case, if an appropriate screen be used to receive the light, we are in reality measuring the illuminating power of the source of light rather than of the light itself. Hence almost as much depends upon the screen on which the light is received as on the light itself. A screen is usually what is called white and by white is meant a screen which reflects every colour equally well; but I would remark that in London the white may become imperceptibly brown, and such colour may interfere materially with accurate results. But the photometry that I am alluding to not only includes the measurement of the illuminating power of light, but the measurement of the light transmitted through bodies of various kinds when they are transparent, like plain glass, or translucent, like ground glass or paper.

* Abstract of first Cantor lecture delivered before the Society of Arts.

Digitized by Google

We may take it, I think, that the first matter we have to consider is the light we have to use as a standard. Parliament, in its wisdom, in 1860, pronounced its standard of light to be the light of a candle, six candles to the pound, each burning 120 grains of sperm per hour, and this is at present the only legal standard known in England, though why, in the name of common sense, such a definition has been continued our legislators alone can guess, when it has been proved to be so faulty. The standard of light for France is the Carcel lamp, which is equal to about 9·5 candles. Now a light from a candle is a very pretty thing theoretically, but, practically, it is anything but practical, as it has the unhappy knack of burning inaccurately, particularly when one is anxious to shield it from draughts. I show you a trace made by photography of the light from a candle burning under normal conditions. The light was admitted through a slit to sensitive paper, and a fresh portion of paper was continually being

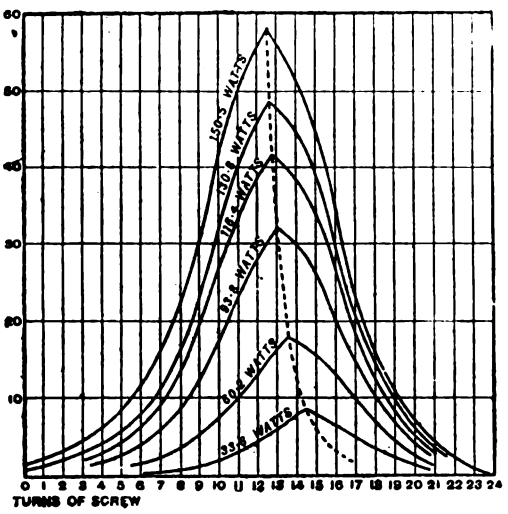

FIG. 1.

exposed. You will now see the irregularity of the burning. Of course, by taking several candles the variation is not so great, but even then you have to be sure that the proximity of the candles to one another does not alter the rate of burning. An Argand burner, however small, will not, during a long series of experiments, differ 1 per cent. in light value. Here we have a proof of this. This small paraffin lamp was allowed to burn for three hours, and you will see that the band it makes is perfectly uniform in appearance, and when the measurement is made of the blackness produced by it on the photographic paper, it proves that my statement is correct.

The apparatus by which these diagrams were made is a very simple one. It consists of a clockwork arrangement drawing a pulley, which pulley is in connection with a drum, which can rotate on its axis. Round this drum is placed sensitive paper, and a box, with a long slit in it, covers the drum. The light is

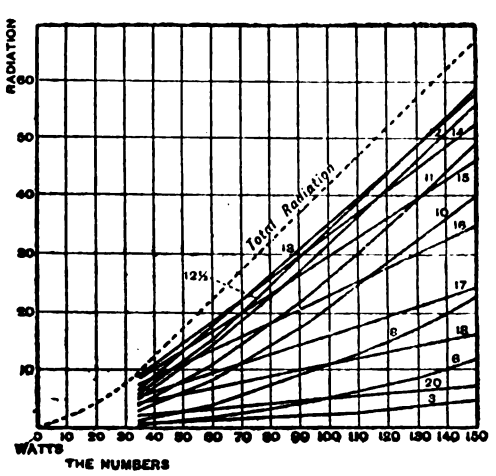

FIG. 2.

placed opposite the slit, which is covered by a moveable lathe, in which is an aperture of a convenient width. As the drum moves, this aperture moves across the slit, and so we have a corkscrew band of exposure produced. With some clockwork the motion is regular in its irregularity, and every tooth of the train can be counted on it by noting the bands of varying exposure, and for this reason the clock was at one time abandoned, and the smooth motion of the sinking of the height in subsiding water was substituted. This gave very good results, but for my purpose the clockwork was sufficient.

The sources of light I have mentioned are what may be called feeble sources of light, and cannot be used when a body is fairly absorptive, if the transmitted light is to be measured. We want in such a case a stronger source of light, and one which is practically constant. Such a source of light we have in the electric arc light. If we project upon the screen an image of the points where the positive pole is slightly behind the negative pole, with a fairly long arc, we become aware that there is a central part, which is higher than any other [shown]. It comes from a depression in the positive pole, and for the last eight years I have been in the habit of using this as a source of light of uniform intensity, and many hundreds of measures have proved it to be so. This, as several years ago I pointed out, was due to the fact that the temperature of this spot was that of the volatilisation of carbon. It is an intense light, and may be taken as 50,000 A.L. per inch of surface, and very useful for a great many purposes, as we shall see as we proceed. Now we call all these lights which I have mentioned white, but it is quite evident that there is white and white if all these be white. I believe myself that Mr. Lovibond's definition of white is a good one, which is the light which is seen in a white fog about midday, and if we compare this light with any other we shall, I think, come back to it as being a very practical white light. Now the electric light is not far from this quality of light, and as such is very useful in comparing the transparency of objects by what is approximately daylight. We can measure the light of each part of the crater passing through a small hole.

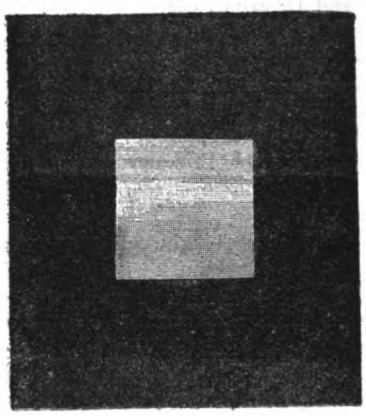

FIG. 3.

We can at once see the difference between all the ordinary lights by a simple experiment. This box is divided into partitions with tissue in front, and in each partition we have a different source of light—a partial gas jet, an Argand gas-burner, a candle, and a paraffin lamp. It will be noticed that the light enclosed in a chimney is much whiter than those burned in free air, but you will also see that all these lights have various depths of yellowness when compared with the electric light. It is quite evident that even supposing they gave the same illumination, that they are not all fit for standard lights. I take it that a standard light in photometry must always have the same quality of light as well as the same quantity of light. Now we can, by appropriate means, make the electric incandescent lamp light of the same visual intervals as a gas jet. The one before us is so, but it is evidently not of the same quality. One of the very best tests that we can make of ascertaining whether any difference in quality exists is to see if, when they are equally strong visually, they give the same photographic results. The amyl acetate lamp is decidedly the worse photographically.

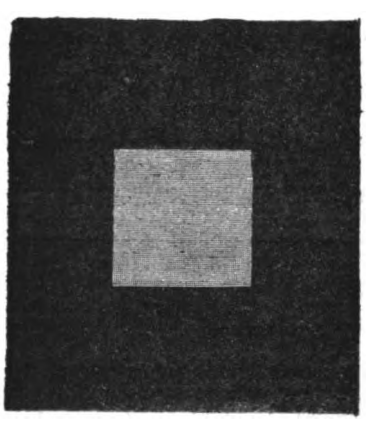

FIG. 4.

Perhaps I can show you why this is. I take an incandescent lamp and cause it to glow: it goes red, to begin with; then I increase the current, it gets yellow, then whiter, and so on, till it is nearly white. I cannot make it as white as the arc light, for the reason that as the temperature increases, the fusing point of carbon is reached, and that, as I pointed out, is the temperature of the crater of the arc light. These temperatures, however, are subject to different amounts of energy expended upon them; and here I have a diagram, showing how, with an increased energy expenditure on the same filament—that is, with an increased temperature—the different rays of the spectrum are altered in proportion. These diagrams are taken from measures made with a linear thermopile, moved through the spectrum. You will see that the higher the temperature, much more rapidly do the rays of high refrangibility increase.

Digitized by Google

The value of the abscissæ in Fig. 1 (in wave lengths) is as follows:

	λ		λ
1·25	5,900	13	14,650
5	7,250	17	20,750
9	9,900	21	27,500

These numbers apply to both diagrams, and in Fig. 2 the numbers attached to the different curves are those which are attached to the abcissæ in Fig. 1.

Let me show an experiment. I will balance an electric light against the amyl acetate lamp, and expose a piece of paper to its action. I will increase the temperature and balance again, and expose another portion of the same paper to its influence for the same time. Notice, please, the difference in the two. You will find that the highest temperature filament is much more

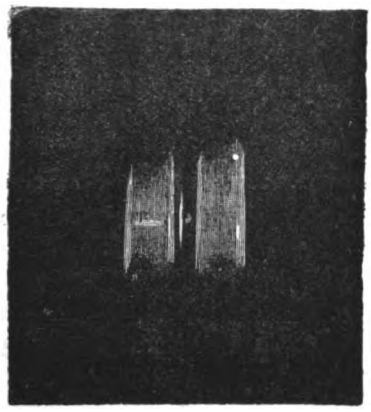

Fig. 5.

"photographic." By this means all lights which are due to the incandescence of solid particles of carbon can be tested as to quality. Make them visually equal, and then see if they are photographically equal. For my own part, I believe that a knowledge of the photographic value of light is essential in the near future, for I cannot help thinking that there will have to be a registration of photometric values for record, independent of the eye, and this must be by photography.

For this purpose the photographic value, and the visual value of every light used, will have to be known and carefully recorded. We shall see soon how these records can be utilised and become of permanent value in themselves, being capable of being measured at any date after being made and remeasured if required. I throw on the screen the photographic values of a candle, an amyl acetate lamp, a gas jet, a paraffin lamp, and an arc light—all made of the same value as a candle visually. You will see that they vary enormously, and the scale of opacity below, which was made by exposing different parts of a plate to a steady light for different times, gives us a means of comparing one with the other.

I have said that all lights which are due to solid particles of incandescent carbon can be tested by means of photography, and I have shown you the deposits which certain lights cause on a photographic plate. There can now be but little doubt that a luminous candle flame is as much due to solid incandescent particles as the incandescent lamp we have been using. The final proof has been long in abeyance, but I think no doubt now can exist regarding it. If a beam of intense light, such as that coming

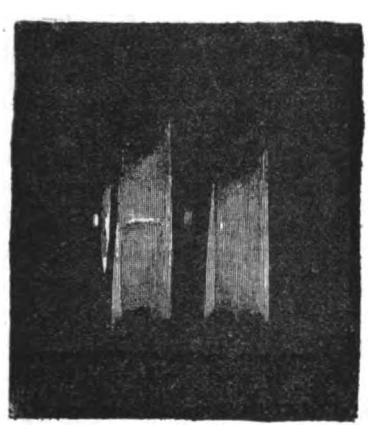

Fig. 6.

from a small image of the sun, be thrown on the flame of a candle, a white beam of sunlight should be seen on the flame, and a beam of white light passing through the flame. Sir G. Stokes examined this white beam in a position at right angles to its direction, and found, by means of a Nicol's prism, that it was completely polarised—that is, that when the Nicol was turned in one direction, the streak of white light in the flame disappeared altogether. This establishes the fact that the luminous part of flame is due to small particles independently of any other proof. It appears to me, therefore, that one is correct in stating that the bright flames are due to measurement carbon. Into the theory of flames I will not further enter at the present time; this is enough for my purpose.

In case there be any doubt amongst you, I will show you some photographs of the phenomena I have taken. Fig. 5 is a photograph of an Argand gasflame, on which the rays of the sun, collected by a lens of about 8in. focus, were concentrated so as to pass along part of the circumference of the cylinder. The Nicol prism was turned in such a direction that the scattered rays would be unaffected in the left-hand photograph, whilst it was turned at right angles to the first direction for the right-hand photograph. In the left-hand figure the track of the beam is readily seen, whereas any trace of it is absent in the right-hand figure. Fig. 6 is the same, but the electric arc light was used in place of the sun. The results are the same. Fig. 7 shows the results when the beam from the electric light is passed through a candle flame. In the one figure a broadish white band is seen, whilst in the other it is absent.

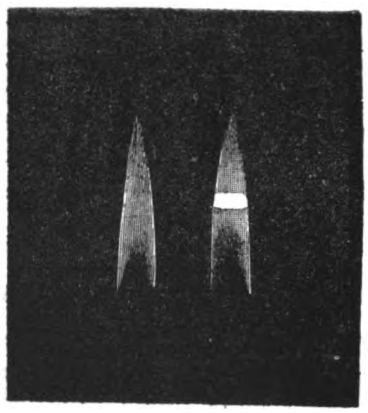

Fig. 7

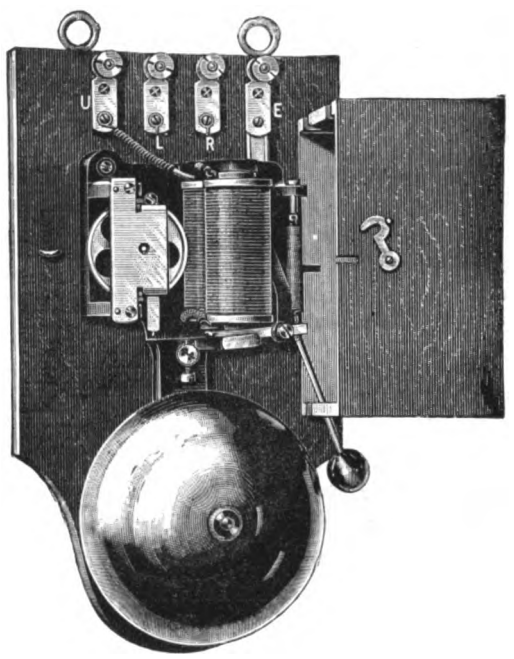
I should here like to correct a very common notion which exists regarding the blackening of ceilings by gas flames. As a matter of fact, the carbon in a gas flame ordinarily is totally converted into carbonic acid. It is the ascending current of heated air that catches up the floating motes in the room and dashes them against the ceiling, to which some cling tenaciously, and gradually the blackening is encountered.

UNIVERSAL BELL.

The annexed illustration shows the universal bell which is being introduced by the International Electric Company, of 55, Redcross-street, Barbican, E.C. It is well known that the shrill tone of an ordinary electric trembling bell sometimes causes annoyance in large offices, hotels, and even in private houses, and in order to overcome this disadvantage the company



have constructed a slow-striking bell, which has met with approval. They have, however, endeavoured to improve upon the first type, so as to make it not only of service where less rattling noise is desirable, but also to make use of the same bell for dispensing with a No. 2 or No. 3 indicator. It will be seen from the illustration that the bell works with a rack and pinion, thus ensuring a reliable contact pressure. The bell can be used either as a slow-striking bell, as a single-stroke bell, or as an ordinary trembling bell, and the four terminals are connected up as follows: terminal U to ring as an ordinary trembling bell, L as a slow-striking bell, E for a single stroke, and terminal R is intended for the return, and should be connected to the zinc pole of the battery. The bell is made in three sizes.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

DIGNITY AND ——.

There is, admittedly, no small interest even to the general public in a periodical chronicling of science topics and problems, much more so, indeed, than the ventilation of individual ideas and fads of the type so often published in the monthly and quarterly political or literary reviews. The value of a "heavy" science periodical is very considerable, so long as it supplies the highest class of criticism, combined with exact and accurate knowledge (but not necessarily expression) of scientific facts. The responsible conductors of the *New Science Review* (a copy of No. 1, Vol. I., of which lies before us) "address themselves to the public at large: their review yields to none in scientific value of its material, and strives to present it in a popular style." Moreover, the new critic "will speak with authority, after weighing evidence with impartiality." How comes it, then, that this very first number contains two elaborate notices of Mr. John Ernst Worrell Keely (of Keely motor fame) alongside of a brief though flattering notice of Tesla? We had thought that further criticism of Keely, the throwing of ridicule upon his absurd scientific gibberish, the characterising his actions and broken promises as being those of a charlatan and humbug — all these were by this time of no purpose, inasmuch as his patrons had either been fully enlightened and disillusioned upon the subject, or else were blind to his faults and foolishness beyond all power of recovery. For Mrs. Bloomfield Moore, the faithful upholder of this nonsensical fabric, to write long and sympathetically of him, is by no means surprising. One can even go so far as to forgive her for entitling her article "A Newton of the Mind," since to liken Keely to the immortal discoverer of gravitation hurts not the latter, and may sooth the former with pleasant flattery. But what shall we say of a man like Julian Hawthorne, the bearer of an honoured name, who writes of scientific creation, and would therein fain bow down and worship also—if he only felt certain that Keely wasn't making a fool of him?

Mrs. Moore states for the benefit of posterity that Keely discovered the "unknown polar flow" twenty years ago, and he now has "command of a vibratory circuit for running machinery both on land and in air." To do this it was necessary to effect a "sympathetic affinity between his machinery and the polar flow, minus magnetism . . . through this system the dynamo will eventually become a thing of the past, and electric lighting will be conducted by a polar negative disc run by a vibratory circuit of sympathetic polar attraction drawn direct from space." Our readers will surely agree with us in thinking, when they have read thus far, that it should be the immediate aim of the well-to-do in electrical circles to endow almshouses and orphanages for indigent dynamo manufacturers and their offsprings. Nay, what scope will there be for the industrial energy of any man in electrical work, when every householder may have his "polar negative disc" supplied with power free gratis for

Digitized by Google

nothing from an indulgent "space," overflowing with vibratory circuits?

We have no space to quote or criticise a tithe of the extraordinary "facts" set forth in this article or to give our readers the pleasure of fathoming the Keely scientific jargon, such choice specimens as "triple subdivision of hydrogen — molecular, atomic, and interatomic; nodal interference in sympathetic negative outreach; positive graduating chladna," and so forth, must stand by themselves, for no amount of context would ever make them clearer. The relief in turning from this "weak, washy, everlasting flood" of talk to the all too brief notice of Tesla's personality and labours in the same review is great enough to be taken as the chief reason for this notice of what would otherwise be a matter of not much importance. There is nothing particularly new in the half-dozen pages given by Lieutenant F. Jarvis Patten to an account of the well-known experiments; under other conditions we might have called the style of the article fulsome to a degree. In substance, however, it appears accurate enough for popular reading; and will doubless serve to educate the man in the street up to an appreciative point of what scientific men are trying to accomplish in the way of improved conditions for human life. It also stands as an antidote to the noxiousness of Keelyism; and for this reason we have not said all the hard things that were at first in mind with regard to the claims made for the new scientific review as compared with the manner in which they are carried out.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

VII.

BY ALFRED E. WIENER.

(*b*) *Energy Dissipated by Hysteresis.*—The iron of the armature core is subjected to successive magnetisations and demagnetisations. Owing to the molecular friction in the iron, a lag, in phase, is caused of the effected magnetisation behind the magnetising force that produces it, and energy is dissipated during every reversal of the magnetisation. The name of "Hysteresis" (from the Greek ὑστερέω, to lag behind) was given by Ewing, in 1881, to this property of paramagnetic materials, by virtue of which the magnetising and demagnetising effects lag behind the causes that produce them.

Although Warburg,† Ewing,‡ Hopkinson,§ and others have made numerous researches about the nature of this property of paramagnetic substances, it was not until recently that a definite law of hysteresis was established. In an elaborate paper presented to the American Institute of Electrical Engineers, on January 19, 1892, Charles Proteus Steinmetz‖ gave the results of his experiments, showing that the energy dissipated by hysteresis is proportional to the 1·6th power of the magnetic density, directly proportional to the number of magnetic reversals and directly proportional to the mass of the iron. This law he expressed by the empirical formula:

$$H_1 = \eta_1 \times B^{1.6} \times N_1 \times M_1,$$

where H_1 = energy consumed by hysteresis, in ergs;
η_1 = constant depending upon magnetic hardness of material ("Hysteretic Resistance");
B = density of lines per cm² of iron;
N_1 = frequency, or number of complete cycles of two reversals, per second;
M_1 = mass of iron, in cm.³

The values of the hysteretic resistance found by Steinmetz for various kinds of iron are given in the following table:

TABLE XXIII.—Hysteretic Resistance for Various Kinds of Iron.

Kind of iron.	Hysteretic resistance. η_1.
Sheet iron, magnetised lengthwise	·0025 to ·005
,, ,, ·0165in. thick	·0035
,, ,, ·015in. ,,	·004
,, ,, ·006in. ,,	·005
,, ,, magnetised across lamination	·007
Iron wire, length-magnetisation	·0035
,, ,, cross- ,,	·040
Wrought iron, Norway iron	·0023
,, ,, ordinary, mean	·0033
Cast iron, ordinary, mean	·013
,, ,, containing ⅛ per cent. aluminium	·0137
,, ,, ,, ½ per cent. ,,	·0146
Mitis metal	·0043
Tool steel, glass hard	·070
,, ,, oil hardened	·027
,, ,, annealed	·0165
Cast steel, hardened	·012 to ·028
,, ,, annealed	·003 to ·009

For the materials employed in building up the armature core, according to this table, we can take the following average values of the hysteretic resistance:

Sheet iron: $\eta_1 = ·0035$,
Iron wire: $\eta_1 = ·040$.

Inserting these values in Steinmetz's equation, and reducing the latter to our practical units, we obtain for the energy loss by hysteresis in any armature having core built of discs or ribbon:

$$w_h = 10^{-7} \times ·0035 \times \left(\frac{\mathfrak{B}_a}{6·45}\right)^{1.6} \times N_1 \times 28{,}317 \times M$$

$$= 5 \times 10^{-7} \times \mathfrak{B}_a{}^{1.6} \times N_1 \times M \quad (36)$$

and in any armature with core of iron wire:

$$w_h = 5·7 \times 10^{-6} \times \mathfrak{B}_a{}^{1.6} \times N_1 \times M \quad . \quad (37)$$

where w_h = energy absorbed by hysteresis, in watts; one watt = 10^7 ergs;
$\mathfrak{B}_a$ = density of lines in armature body per square inch of core section;
N_1 = frequency, in cycles per second, = $\frac{N}{60} \times P$;
N = number of revolutions per minute, P = number of pairs of poles;
M = mass of iron, in armature core, in cubic feet; 1 cubic foot = 28·317cm³.

The mass, in cubic feet, for both drum and ring armature is

$$M = \frac{d_a''' \times \pi \times l_a \times b_a \times k_1}{1{,}728}; \quad . \quad . \quad . \quad (38)$$

d_a''' = mean diameter of armature core, in inches;
l_a = length of armature core, in inches;
b_a = radial depth of armature core, in inches;
k_1 = ratio of net iron section to total cross-section (see Table XVIII., Chap. 12);
1,782 = multiplier to convert cubic feet into cubic inches.

Formulæ (36) and (37) can be rendered more convenient for practical use by uniting the terms $5 \times 10^{-7} \times \mathfrak{B}_a{}^{1.6}$, and $5·7 \times 10^{-6} \times \mathfrak{B}_a{}^{1.6}$ respectively, into one factor, η, the *factor of hysteresis*—that is, the energy absorbed by hysteresis in one cubic foot of iron, when subjected to magnetisation and demagnetisation at the rate of one complete cycle (two reversals) per second.

For convenience, the author, in Table XXIV., has calculated the numerical values of these hysteresis factors, η, for all core densities from 10,000 to 125,000 lines per square inch, thus simplifying the equation for the hysteresis loss into the formula:

$$w_h = \eta \times N_1 \times M. \quad . \quad . \quad . \quad . \quad (39)$$

The values of η contained in this table are graphically represented in Fig. 14, two different scales being used in plotting the curves, as designated.

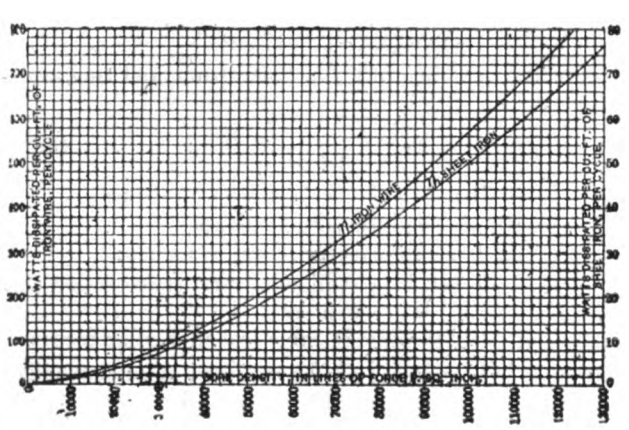

FIG. 14.

With regard to the exponent of $\mathfrak{B}_a$ in formulæ (36) and (37), which Steinmetz found to be approximately = 1·6 over the whole range of magnetisation, Ewing,* by very recent investigations has found that it varies at different magnetisations. In the case of thin sheet iron (·0185in.), for instance, the hysteretic exponent ranged as follows.

* J. A. Ewing and Miss Helen G. Klaassen, *Phil. Trans.* Royal Society; *Electrical Engineer*, XVII., page 417 (May 9, 1894).

TABLE XXV.—Hysteric Exponents for Various Magnetisations.

Magnetisation. In lines per c.m.^{2} (Gausses).	Magnetisation. In lines of force per square inch.	Hysteretic exponent.
200 to 500 ...	1,300 to 3,000 ...	1·9
500 ,, 1,000 ...	3,000 ,, 6,500 ...	1·68
1,000 ,, 2,000 ...	6,500 ,, 13,000 ...	1·55
2,000 ,, 8,000 ...	13,000 ,, 50,000 ...	1·475
8,000 ,, 14,000 ...	50,000 ,, 90,000 ...	1·7

Although Ewing thus has shown that no formula with a constant exponent can represent the hysteretic losses within anything like the limits of experimental accuracy, he concludes that Steinmetz's exponent 1·6 gives values which are nowhere so grossly divergent from the truth as to unfit them for use in practical calculations. This conclusion holds particularly good for the densities applied in dynamo-electric machinery, as from the table given above can be seen that for densities between 4 and 14 kilogausses (25,000 and 90,000 lines per square inch respectively), see Table XVII., chapter 12, the hysteretic exponent, according to Ewing's experiments, varies from 1·475 to 1·7 the average of which is 1·59, indeed, a good agreement with Steinmetz's value.

(To be continued.)

NOTES ON ELECTRIC TRAMWAYS IN THE UNITED STATES AND CANADA.*

BY H. D. WILKINSON, MEMBER.

(Continued from page 69.)

During the progress of this litigation a new tramway company was financed by those most largely interested in the telephone company, with the view of proving that double-trolley was the only way out of telephone interference, and to force the hands of the single-trolley company. Mishaps in winter, however, in the earliest days of its adoption, favoured the final appeal above alluded to, and ended in metallic returns being put on telephone lines instead. The position remains unaltered to-day, and both trolley systems prosper. I found that the insulation of the double-trolley lines was good, so far as the overhead construction was concerned; but that it frequently broke down at the motors, thus putting one or other trolley line to earth. To show what kind of insulation existed, my friends and I boarded a single-trolley car, stopped it, and pulled the trolley arm off the single wire on to one of the double-trolley wires; the lamps lit up inside the car showing an earth on one main of about 200 volts. The leak was not sufficient, however, to run the car, but it appeared that in wet weather this was frequently done. Again, in the Hunt-street station, an earth indicator was permanently fixed, consisting of two rows of five lamps in series. Each row was connected between one of the trolley wires and earth, and I observed during my visit to this station that one of these rows was lighted up to nearly full candle-power. The light was fluctuating slightly, which appeared to indicate that the earth was on a moving car; at all events, I was informed that such earths were of frequent occurrence, and went off as suddenly as they came on, but did not affect good working Earths on a line were "spotted" after all cars were home for the night by switching off one section after another while full power was kept on. The leakage current on two lengths of twelve and nine miles of double track joined in multiple with all cars off was 12 amperes under the full pressure of 500 volts.

The cost of street work in America for double-trolley construction is about £650 per mile, the items being as follows:

	£	s.	d.
100 iron poles	260	0	0
100 hangers	17	0	0
100 solder cars	5	0	0
70 strain insulators	4	9	8
3,000ft. span wire	12	0	0
10,560ft. No. 1 copper trolley wire	84	9	8
5,280ft. No. 0000 feed wire	211	4	0
25 3ft. cross-arms	0	15	0
50 glass insulators	0	12	0
200 sacks of cement	12	0	0
15 loads broken stone	4	10	0
5 loads sand	0	15	0
Labour and superintendence	45	0	0
	£657	15	4

This is about one-third more than the cost of single-trolley construction; but against this must be put the dispensing with bonds. While this system is out of place in cities and confined

* This paper, which will be discussed before the Institution of Electrical Engineers, is taken from the *Journal* of the Institution.

Digitized by Google

thoroughfares, and, indeed, wherever span wires must be used, I believe it offers some advantages for heavy passenger traffic or goods traffic in suburban districts. It offers immunity from leakage currents to earth, for such can only take place when more than one earth is on the line. There is therefore no anxiety as to electrolytic action on pipes, even with the heaviest currents, no interference with telephones, and it is not necessary to bond the rails. With neat iron poles and ornamental cross brackets the line is not at all unsightly in the centre of the road. On some lines the appearance is improved by clusters of incandescent lamps, with reflectors, on every second or third post, and all feeder cables kept underground. The only objection to the system is the amount of overhead work at curves, turn-outs, and crossings; but it certainly holds its own in Cincinnati for smooth and rapid transit, and has proved itself a commercial success. On the table are some photos of the city for members to examine, showing some of the overhead construction. I have

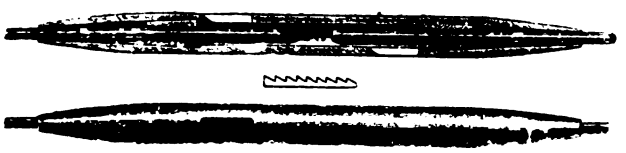

FIG. 11.

here also a specimen of the Kisinger splicing tube, by which breakages in trolley wires are rapidly repaired, Fig. 11. I witnessed two breakages in one street which took only five minutes each to repair by means of these tubes. The broken ends are pulled up and put in the tube, and then the dogs slipped in through the slot. When the tackle is slacked off, the ends are locked and an excellent electrical joint made without soldering. For working at the wires, an emergency wagon with folding ladder is used, and joints have been made in 3½ minutes, including picking up broken ends from the street.

I now pass to the consideration of underground conduit lines, also using an insulated return. During my stay in Chicago, the extensive plant of the North Side Tramway Company, consisting of gas motors fixed to special cars, suffered almost complete destruction by fire. As there had been serious complaints of the noise and smell of these gas motors, the company endeavoured to get a clause revoked in their franchise which prohibited their using an overhead trolley line. Their intention to equip their line in this manner, however, met with great opposition from

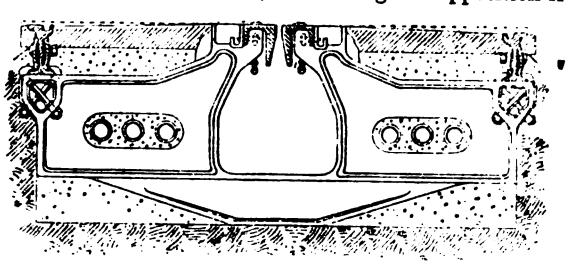

FIG. 12.—Yoke.

property holders, tradesmen, and insurance companies, and the clause was not struck out by the City Council. Previously, however (in March, 1892), in consequence of this clause, the company had equipped about a mile and a quarter of their line electrically with an underground conduit on the Love system. I found this in successful operation last year, and made a few notes on it, which I hope may prove of interest. The illustrations, Figs. 12 and 13, show sections of the line construction and roadway. The depth excavated below the road level is only 2ft., involving no trouble or expense while laying the track in diverting pipes along the route, as is so often necessary in laying a cable track. The slot rails are in 32ft.

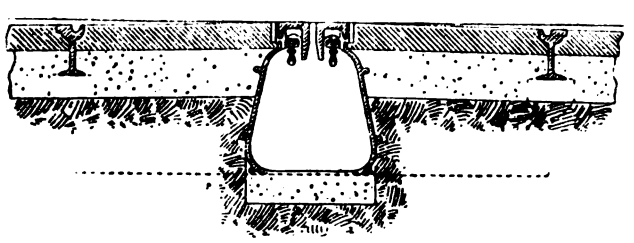

FIG. 13.—Conduit.

lengths, and bolted to the yokes every 4ft. Pockets, or small hand-holes, are provided in the road over every bolt, so that, if required, the rails can quickly be removed, and the conductors and insulators exposed to view. The slot rails are spaced for a ⅝in. slot, and shaped with 5in. inside lips, so as to shed water into the conduit clear of the wires. The track rails are held by claw bolts to the yokes, as shown, and the whole construction rests on a bed of 6in. concrete, and is packed round with concrete as a bed for the stone blocks of the roadway. In the webs of the yokes spaces are left for laying pipes to contain feeder wires, the conductors being in sections of 500ft. The conductors are of bare copper rod, nearly ½in. diameter, grooved longitudinally, and suspended from loose-fitting gunmetal clips, or ears, as shown, Fig. 14. The stalk of each clip is secured to a block of pressed mica or other insulating material, B, which is suspended from two shoulder-bolts bolted to the yoke. To allow for expansion of the conductors, the blocks are free to move about 2½in. on the rods. With the trolley

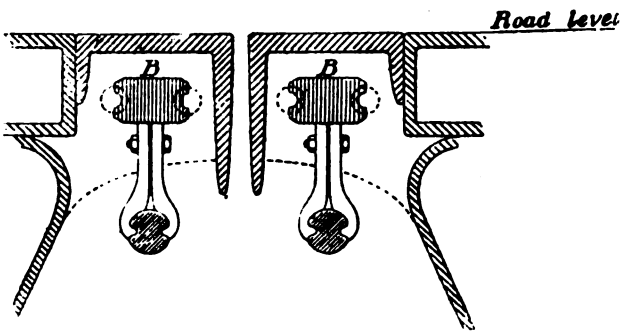

FIG. 14.

wheels travelling in the direction of the arrow, it was found that the blocks shifted a little in the reverse direction every time the trolley wheels passed, and it was necessary to put stops at S, Fig. 15. The insulators are fixed to every alternate yoke, at a distance apart of 9ft. on the straight run. On curves, however, they are closer together, and stronger supports are used, the conductor being circular in section, and clipped in ears having circular jaws, as shown in Fig. 16, which are afterwards filed round below, so as to offer no resistance to the

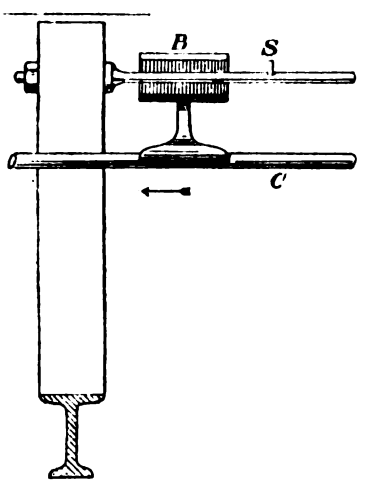

FIG. 15.

trolley wheel. The trolley wheels bear upwards on the underneath side of the conductor, exactly as in overhead lines. The illustration, Fig. 17, shows the arrangement with spring for keeping tension on trolley wire, and back stop for keeping the wheel in place on the wire. The plate travelling in the slot and supporting this gear is of ½in. steel, and 4½in. wide. The trolley arms are jointed to take lateral as well as vertical movement, and thus follow every change of direction of the conductors. The line in Chicago is in the form of a triangle a little

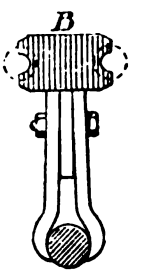

FIG. 16.

over 1¼ miles long, with three straight lengths and three curves, and in one place it crosses over the cable line. The motor cars (which also carry passengers) haul the trailers with passengers left by the Lincoln-avenue cable cars and North Halstead-street horse cars round Fullerton and Webster Avenues. This was the first line on this system, and, as might be expected, some difficulties were met with. These were chiefly due to the breakage of insulators, expansion of conductors, and snow and ice in the conduit. Boys were also a nuisance, stuffing wire into

Digitized by Google

slot, which jammed the trolley wheels and short-circuited. I found that in July last there had been five stoppages, two in August, and none at all the following three months. Two of the stoppages were, however, due to burnt-out armatures. Brushes were used attached to cars for sweeping out water and dirt from the conduits into sump-holes every 100ft., which were afterwards pumped out by hand. Water gave no trouble at all, except when it froze in the conduit. Wide extremities of temperature are met with in Chicago, being 15deg. to 20deg. below zero in the winter, to 90deg. in the shade in the summer, and expansion gave a good deal of trouble at first, especially at curves, where the conductors sagged till they nearly touched the side of the iron conduit, upon which the trolleys made earth and short-circuit by touching the sides. This was overcome by dividing the conductors into sections of 500ft. to 600ft., and covering the adjacent ends with a long sleeve. Powerful compressed springs on either side of the sleeve were used as shown in the illustration, Fig. 18, which drew the ends together and took up the expansion.

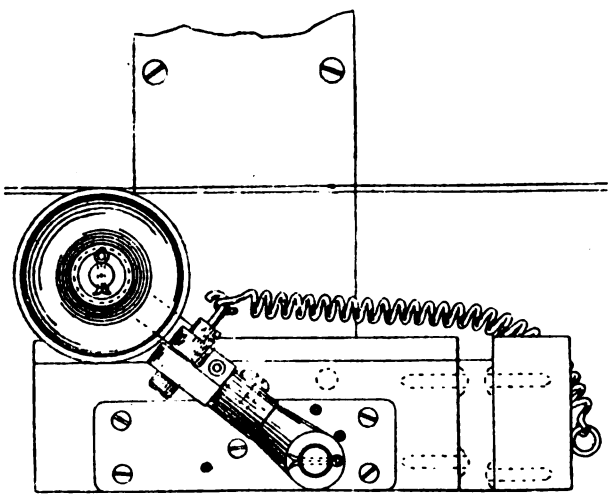

FIG. 17.

At the Milwaukee Convention Mr. M. D. Law read a paper on this system as now operated in the city of Washington (district of Columbia), in which he mentioned the improvements introduced by the Rock Creek Railway Company using the system in that city. I subsequently saw this line at Washington, and found the construction perfected in many details, and the system giving completely satisfactory service, uninterrupted since its inauguration in March, 1892. The line was a credit to this well laid out city, and anyone who could see the smooth and regular running of the cars, with no overhead wires, would say there was a great future for such a system in city traffic. The line of the above company extends some 6½ miles in the suburbs with the overhead trolley system, but at the city boundary it changes to underground trolley. The change from one to the other only involves fixing the trolley bar and switching off the earth connection, which I timed to take 20 seconds. The line then continues along U-street for 1½ miles with double track. On the return journey, close to the junction, the cars have to take a sharp curve, and take an ascent of 1 in 40 at the same time, which they do easily. The insulators and supports

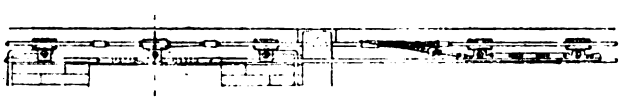

FIG. 18.

at the curves are all strengthened, and the conduit is made 20in. deep by 14in. wide, the extra width allowing ample clearance between the wires and the sides of the conduit. The yokes are also put at 4ft. centres instead of 4ft. 6in., and the conductors are of §in. hard drawn copper. A separate power house was erected to supply the underground system, as it was desired by Mr. Law and Mr. Herbert Claude, the engineers to the company, to thoroughly test the system. Leakage to earth, as shown by a voltmeter between the conductor and earth, was only 0·1 per cent. even in the stormiest weather, and the ammeter remained dead at zero when the full E.M.F. was on and the cars all off. In the wettest weather it was a common thing to find dusty insulators and perfectly dry conductors on removing the slot rails ; this condition being due to the natural draught in the conduit and the umbrella nature of the slot rails. On two or three occasions, however, severe rain storms had flooded the conduit and immersed the wires, but the cars ran without delay. With four fully loaded cars on the line the drop was only 3 volts. The trolley wires were in sections, with main and return feeders, switches, and cut-outs to each section, placed in manholes every 500ft. on the straight run.

(To be continued.)

THE SOUTH STAFFORDSHIRE ELECTRIC TRAMWAY.

WORKING RESULTS.

In the *Electrical Engineer* of November 18, 1892, was published a lengthy illustrated description of the South Staffordshire electric tramway, which commences at a junction in Wednesbury with the line from Handsworth, passing through the Market-place, along the Wednesbury-road to the Pleck, where it is joined by another section of the electric line which connects that point with Darlaston. It then passes along the Walsall-road to Walsall Bridge, where it again divides, one section going to Rushall and the other to Bloxwich. Mr. Alfred Dickinson, engineer to the company, has now contributed to the *Proceedings* of the Institution of Civil Engineers a paper describing the line and giving working results. As we have already fully described the tramway, we content ourselves with reproducing from the *Proceedings* the following particulars concerning the working results.

After the formal inspection on behalf of the Board of Trade, the electric system of lines was opened for traffic on January 1, 1893. From that date to February 28, 1894, the cars have run 310,115 miles, and have carried 1,920,185 passengers. From January 1, 1893, to December 31 inclusive, the cars ran 262,692 miles, and carried 1,668,057 passengers, the local authorities, the public, and the directors of the South Staffordshire Tramways Company being completely satisfied with the results. The line is worked by the Electric Construction Corporation under a contract with the tramways company, and in dealing with the working cost for purposes of comparison the author proposes only to deal with the charges where a direct comparison can be made—viz., all those for running and maintenance, minus traffic charges and maintenance of permanent way. The following statement shows the cost of working several systems of tramway lines in 1893 :

COMPARATIVE STATEMENT OF COST PER CAR MILE FOR RUNNING AND REPAIRS. 1893.

Charges.	South Staffs Tramways Co. Wilkinson locomotive steam-engines vertical boilers.	Birmingham Midland Co. Kitson locomotive steam-engines.	Dudley and Stourbridge Co. * The items referring to steam traction include repairs of every description ; those to electric accumulator traction include stationary engines and boilers, dynamos motors, batteries, switches, and all repairs pertaining to an electric installation ; to cable traction—stationary engines and boilers, cable, pulleys in road, cars, and all repairs incidental thereto ; to overhead electric traction—stationary engines and boilers, dynamos, motors, poles, feeders, overhead wire, cars and all other repairs in connection with an electric system.

† This item includes an amount taken from depreciation fund.

The average cost for fuel on the four lines worked by steam is 2·00d., electric accumulator 1·76d , cable 0·60d., and overhead electric traction 0·48d. per car mile run.

Hitherto it has been most difficult to obtain a direct comparison between electric traction and any other system, but such now is not the case, at any rate, so far as the South Staffordshire line is concerned, because the electric

Digitized by Google

cars are running upon lines previously worked by steam. When designing the system, the author was in doubt as to the amount of steam-engine power to provide in the generating station per car on the lines, and how to arrange its subdivision, as the number of cars upon the line at different times would vary considerably. However, he ultimately decided to split the power into three elements, so as to be able to reduce it to suit the number of cars running upon the line at any given time. He was prepared, from his experience in the working of the cable line in Birmingham, for a considerable variation in the load; but he certainly never anticipated that its range would be so great in so short a time as he finds to be the case. With 16 cars on the line, the output has been found to vary as much as 233 e.h.p. in the space of five seconds, and with 11 cars upon the road as much as 202 e.h.p in the same period. Taking into account even the extraordinary fluctuations caused during holiday times, it is satisfactory to observe that the cost per car mile for fuel is below that of cable traction; and in this comparison it is well to bear in mind that the power on the cable route is distributed over only three miles of route with double the number of cars running, as against eight miles of route on the electrical section. By many engineers the problem of arranging an economical mechanical plant for working a tramway may be considered simple; but the physical conditions of any district, the ever-varying condition of a tramway rail, demanding within a few hours as much as 50 per cent. increased tractive power, are more important factors in this problem than they are generally considered to be. It is a curious fact that as soon as mechanical traction of any kind is introduced, the public demands that gradients shall be ascended and descended at a constant speed; and the South Staffordshire electric system is able to comply with that demand. During the winter, when snow was on the line, the electric cars kept correct time, whilst the steam cars lost half an hour in a run of six miles. It may seem astonishing that an electric car carrying 40 passengers is occasionally called upon to exert 48 e.h.p., but of this fact evidence is afforded by the author's trials.

He has recently had a motor that had been running for 14 months taken from a car and tested with a "Prony brake," when its mechanical efficiency was found to be 78 per cent.—a most satisfactory result. At the same time he tested the torque of the armature with a current of 48 amperes taken from the trolley wire under normal conditions, and found this would raise a weight of 141lb. at the end of a lever 7ft. long. This is equal to a torsional force of 1,692lb. weight on the armature. Testing with a dynamometer the amount of pull to be obtained on the drawbar, with all the resistance cut out and both motors in circuit, he found it was 1 ton 7cwt. He then tested a Wilkinson engine at a boiler pressure of 150lb., with cylinders 7⅞in. diameter geared 1⅔ to 1, and this gave exactly the same pull.

The author had at first considerable misgiving as to the probable amount of wear and tear upon the trolley-wire, and after running for 14 months it is satisfactory to find that it is scarcely possible to measure it.

TELEGRAPHIC COMMUNICATION BY INDUCTION BY MEANS OF COILS.*

BY CHARLES A. STEVENSON, B.Sc., F.R.S.E., M.I C.E.

In 1892, I suggested that communication could be established between ship and ship by means of coils,† and as a trial of the system on a large scale has recently been made with the view of establishing communication between North Unst lighthouse, situated on Muckle Flugga, and the mainland (Fig. 1), thence to the lighthouse station at Burrafiord, a distance of two miles, a record of the trials may be of interest to the society.

The induction of one spiral on another has been long known, but with a very strong battery current it has been found impossible to bridge a greater distance than 100 yards,‡ so that as a means of practical communication it was impossible. It has also been long known that communication could be established by means of parallel wires, and disturbances in wires no less than ten miles apart had been detected. For many years this system has been under discussion, and only last month a series of elaborate experiments at Loch Ness has been made by Mr. Preece on this parallel wire system on the most approved methods; but I trust to be able to show that the parallel wire system * must give place to the method of communicating by coils.

It is evident that if two coils are placed so that their axes are coincident, their planes being parallel, or if they be placed so that their planes are in the same plane, they will be in good positions to expect electric currents sent in one to be apparent by induction in the other. For a given diameter, and where the electrical energy is small and the number of turns small, the first position is best, but where the energy is great and the number of turns great—in fact, when it is wished to carry the induction to many times the diameter of the coils—then it will be found that it is better to let the two coils be in the same plane, as, when the axes are coincident and the coils a great distance apart in comparison with the diameter, the difference of distance from one side of the coil, say top of primary coil to top and bottom of secondary, becomes almost a vanishing quantity; whereas, when the coils are lying on their side in the same plane, the difference of distance from back of primary to back of secondary, and from front of primary to front of secondary, does not fall off so fast, and consequently is more efficacious. Besides, it becomes impracticable to erect coils of large diameter with their planes vertical, but it is easy to lay them on their sides. It is almost impracticable to introduce a core in these large coils, although the effect would thereby be intensified, and where compactness is necessary a core is advantageous. A number of experiments were made in the laboratory to discover the laws of the action of coils on each other, with a view of calculating the number of wires, the diameter of coils, the number of amperes, and the resistance of the coils that would be necessary to communicate with Muckle Flugga, and, after a careful investigation, it was evident that the gap of 800 yards could, with certainty, be bridged by a current of one ampere with coils of nine turns of No. 8 iron wire in each coil, the coils being 200 yards in diameter.

Two coils, about 850 yards centre to centre, were erected at Murrayfield (and I may here thank Mr. Gibson, telegraph engineer of the General Post Office, and his staff, and also Mr. Asher of the National Telephone Company, and Messrs. Clement and Francis of the North British Railway for their valuable assistance), one coil being on the farm of Damhead, and the other on the farm of Saughton, and as nearly as was possible on a similar scale, and the coils of similar shape,† as was wished at Muckle Flugga.

On erecting the coils, communication was found impossible, owing to the induction currents from the lines from Edinburgh to Glasgow, the messages in these lines being quite easily read, although the coils were entirely insulated and were not earthed. The phonopore which the North British Railway Company have on their lines kept up a nearly constant musical sound, which entirely prevented observations. On getting the phonopore stopped, it was found that 100 dry cells, with 1·2 ohms resistance each and 1·4 volts, gave good results, the observations being read with great ease in the secondary by means of two telephones. The cells were reduced in number down to 15, and messages could still easily be sent, the resistance of the primary being 24 ohms, and the secondary no less than 260 ohms. If the circuit had been of good iron, with soldered joints, and well earthed, the resistance should have been only 60 ohms. The induced current therefore generated in the secondary would therefore be in the ratio of 480 to 210, or with this great resistance, allowing for the resistance in the two telephones in multiple, we got practically only half the current we would have got if the line had been a permanent in place of a temporary one.

A trial was made of the parallel wire system, and with 20 cells the sound was not heard, and with 100 cells it was heard by me as a mere scratch in comparison with the sound with the coil system with 15 cells. A trial was made with a phonopore, and the coils worked with 10 cells with perfect ease, and a message was received with only five cells. Speech by means of Deckert's transmitter was just possible, but it is believed that if the hearing circuit had been of less resistance it would have been easy to hear.

It is difficult to understand how this system of coils, in opposition to the parallel wire system, has not been recognised as the best. For, assume that with the arrangements we had, we heard equally well with 100 cells by both systems, both having the same base (200 yards), then by simply doubling the number of turns of wire, and using thick wire of low resistance, the effect would have been practically doubled, whereas, by the parallel wire system, there is nothing for it but to increase the battery power, which, for practical working, becomes an impossibility. The difficulty of the current is thus removed by using a number of turns of wire. There is shown on the following diagram (Fig. 3) the result of simply increasing the diameter with a given length of wire, keeping current and resistance the same. It shows that the larger the diameter the better; in fact, with a given length of wire, a straight one is the best. But this is not practicable; what is wanted is to get induction at a great distance from a certain given base with a small battery power, and the laboratory experiments and trials in the field show that the way to overcome the difficulty of the current is by using a number of turns of wire. The secret of success is to apportion the resistance of primary and secondary and the number of turns on each to a practical battery power.

Coil System.—(1) At 850 yards from centre to centre of coils averaging each 200 yards diameter, it was found that, with a phonopore, messages were sent with 5 dry cells. The resistance in primary being 30 ohms, and the resistance of secondary 260 ohms, the current being ·23 ampere which, with nine turns, gives two

Digitized by Google

ampere turns. (2) With a file as a make and break it worked with ten cells, giving ·4 ampere or 3·6 ampere turns.

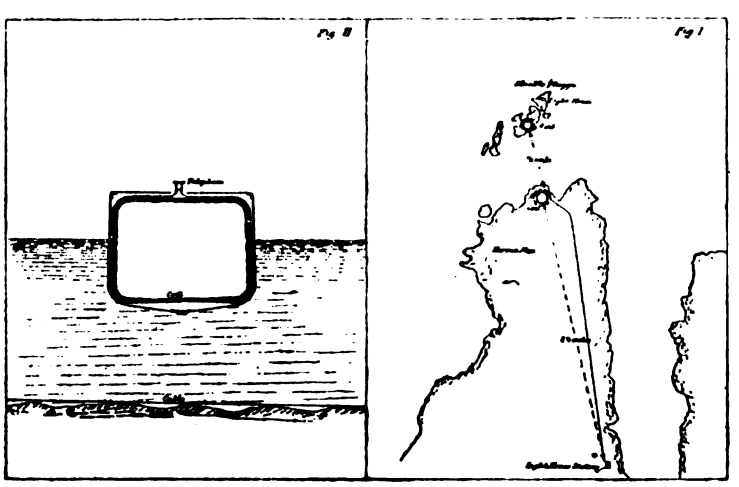
Parallel Wire System.—(3) With a file as a make and break, and with parallel lines earthed, it was heard with 100 cells, giving 1·1 ampere. Fig. 4 shows the variation with number of turns on one coil, the current and resistance remaining constant.

The calculation of the diameter necessary to hear a given distance is simple, from the fact that the hearing distance is proportional to the $\sqrt{}$ of the diameter of one of the coils, or directly as the diameter of the two coils, so that, with any given number of amperes and number of turns to hear double the distance requires double the diameter of coils, or double the number of turns, and so on. But this is within certain limits, for when the coils are close to one another the law does not hold.

There is one point which seems to have been cleared up by these trials, which has even this month been a subject of discussion in London, and that is, whether or not the parallel wire system is actuated by induction or conduction, and there is little room for doubt, from the fact that both circuits were insulated, and was thus a case of pure induction, that to a large extent it is induction; in fact, that they act together, and it will depend how the ends are earthed, or, in short, what is the distance bridged in comparison to the breadth of base, which predominates. Where the wires are [illegible] comparison with the distance bridged, conduction will be the [illegible]working factor, but when the base is small, and the distance bridged is large in comparison, induction will be the main factor, and the number of turns then increases the effect.

The primary coil was insulated in the Murrayfield trials, as at Muckle Flugga it must be so, the impracticability of making and maintaining the sea connections necessitating this, and the secondary was earthed, as is most convenient at Muckle Flugga. When the secondary was also made a complete insulated metallic circuit, there seemed to be little difference in the result.

There is one other point to which reference must be made. Mr. Preece has been repeating the experiments brought before this society on January 30, 1893, and he found, if rightly reported, that when the hearing wire was floating he got results, but when it was allowed to descend that no observations could be got; he attributes this to reflection from the surface of the water; this, however, is unlikely, as the reason that no sounds were then heard was that the major part of the wire lay on an equipotential line. Electro-magnetic waves enter or leave salt water practically unimpaired, as the following diagram (Fig. 5) will show, where A is a wire suspended 10ft. above salt water and B is a wire sunk in salt water. On trial, it was found, as stated in my paper read before this Society in January, 1893, that there was no practical difference in air or salt water to the propagation of electro-magnetic waves, in or out the distance to which waves went—*i.e.*, the distance to which the currents could be heard being immaterial whether the detector was sunk or in air.



It has been attempted to be shown that the coil system is not only theoretically but practically the best. Meantime, my brother has recommended the Commissioners of northern lighthouses to erect the coil system at Muckle Flugga, and the Commissioners have approved, and I hope that we may soon hear of this novel system of communication being erected at the most northern point of the British Isles, where the laying down and after-maintenance of a submarine cable is practically impossible. This system is also applicable to our warships, to assist in their manœuvering, by the establishment of instantaneous communication unaffected by wind or weather.

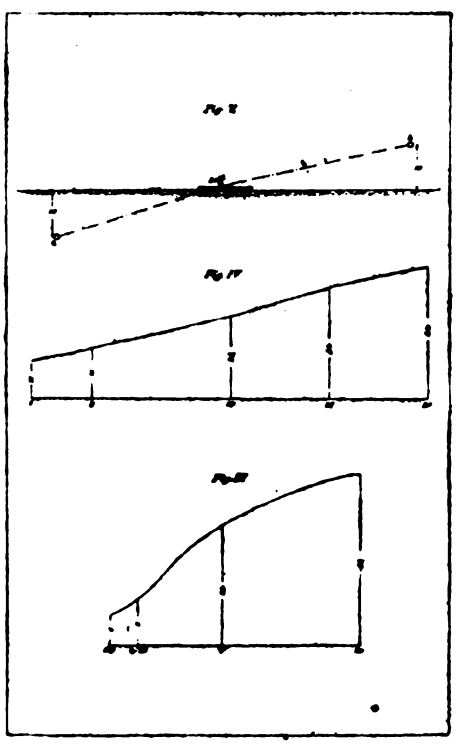
The application of the coil system to communication with light-vessels is obvious, namely, to moor the vessel in the ordinary way, and lay out from the shore a cable, and circle the area over which the lightship moorings will permit her to travel by a coil of the cable the required diameter, which will be twice the length of her chain cable. On board the vessel there will be another coil of a number of turns of thick wire. Ten cells on the lightship and ten on the shore will be sufficient for the installation. The system erected at Kentish Knock and other light-vessels is expensive in moorings, and is liable to derangement, and requires special appliances; whereas, by the coil system there can be no derangement, and the vessel can be moored in the ordinary way. A call arrangement and telephones complete the installation.

SUBMARINE TELEGRAPHY TO THE FAR EAST.

The twenty-fifth anniversary of the establishment of submarine telegraphy to the Far East was celebrated on Friday evening at the Imperial Institute by a banquet, which was given by the Eastern and the Eastern Extension, Australasia, and China Telegraph Companies, followed by a reception which was attended by the Prince of Wales. Sir John Pender, M.P., the chairman of the two companies, presided at the banquet, which was served in the Grand Hall.

After the loyal and other toasts had been given, the **Lord Mayor** followed with the toast of "Submarine Telegraphy in its Commercial Aspect."

The **Chairman**, in acknowledging the toast, said that when it was almost impossible to raise money for the 1865 cables, the Telegraph Construction Company was formed, and they were indebted to that company for the good work they then and had ever since done. Even in those early days it was proved by their late colleague and managing director, Sir James Anderson, to be possible to pick up and repair a cable in 2,000 fathoms of water. For that great work all credit was due to Sir J. Anderson, who devoted the best years of his life to the development of submarine telegraphy. They were also indebted to Sir William Thomson, Cromwell Varley, Fleeming Jenkin, and many other distinguished men for their scientific inventions, which enabled submarine telegraphy to achieve the great scientific and commercial success it had since become. At the present time there were 11 cables in the Atlantic, and another was in course of submersion, so that with the aid of duplex working, for which they were indebted to Dr. Muirhead and others, the carrying capacity was practically equal to twice that number of cables. The first attempt to provide the public with submarine telegraphs to the East was in 1859, when a cable was laid down the Red Sea and along the coast of Arabia and through the Persian Gulf to Kurrachee. Unfortunately this cable worked only a few days in its entire length, and it was afterwards abandoned. The success attending the Atlantic cable caused the idea of submarine telegraph communication to the Far East to be again considered and carried into effect by the formation of various companies, which were afterwards merged into the Eastern and Eastern Extension Telegraph Companies. Twenty-five years ago on the previous day the company that laid the submarine system from Great Britain to the Far East was registered. At that time the nucleus of the present system of Eastern telegraph consisted of about 900 miles of cable, with a capital of £260,000. That day they owned 51,325 miles of cable, and had a joint nominal capital of over nine millions sterling. Two years after the registration of the Eastern Companies the whole submarine system between Great Britain and China was completed and in working order. A year later the Australian colonies enjoyed the benefits of daily intercourse with the mother country and the rest of the world. At present the total mileage of submarine cables was in round numbers 152,000 miles, of which 90 per cent. had been provided by private enterprise and 10 per cent. by the various Governments, costing altogether over 40 millions sterling. The total length of land wires throughout the world was over 2,000,000 miles, estimated to have cost about £65,000,000. If the cables and land lines were added together, a combined capital was represented of £106,000,000. When a Pacific cable was really required, the companies which he represented would not be



Digitized by Google

found backward in meeting public requirements. He concluded by acknowledging the good work and hearty co-operation which they had received from their Danish friends, the Great Northern Telegraph Company, and he also desired to acknowledge the good work and co-operation which they had always received from their officers and staff throughout the service.

Other toasts having followed, the banquet terminated. Subsequently the chairman and his co-directors returned to the vestibule, where the Meister orchestra was stationed, and where at about 10 o'clock they began to welcome the guests to the reception. On their arrival the Prince of Wales and the other Royal guests were received by the Lord Chancellor, Sir F. A. Abel, and Sir Somers Vine, and were conducted to the vestibule, where Sir John Pender and his colleagues welcomed them. The Royal party and suite then proceeded to the eastern *foyer* in the upper central gallery, where they inspected an interesting exhibition of cable telegraph instruments and appliances.

In the course of the evening the Prince of Wales despatched telegrams to the Viceroy of India and to the Governor-General of Canada. Telegrams were also despatched by the Prince of Wales to the Governors of other Colonies, and the Royal party were afterwards entertained at supper.

THE HISTORY OF WOODHOUSE AND RAWSON UNITED, LIMITED,

As Detailed in the Bankruptcy Court.

FRIDAY.

The public examination of the directors and officers of this Company was continued on Friday before Mr. Registrar Hood, at Bankruptcy-buildings, Carey-street, Lincoln's-inn.

Sir Rawson W. Rawson was recalled and further examined by the Official Receiver. He stated that he could not give details of the profits which he said, in the course of his speech at a meeting of shareholders held in January, 1891, had been made. He was anxious to give all the information and assistance in his power, but his memory as to matters which occurred three or four years ago was very defective. He was satisfied that the statements he made were justified at the time. It appeared from an analysis of the accounts that about £80,000 out of the total profits of £100,000 was represented by the profits made over three transactions.

The **Official Receiver**: Do you think that these profits were not casual and accidental and were likely to be maintained?

Witness said he thought that they might be repeated, and therefore did not consider them exceptional. The directors had a prospect of obtaining a very valuable French concession and other contracts. He became aware that his son, Mr. F. L. Rawson, was connected as a director with the Phœnix Trust Company and Baron Grant.

The **Official Receiver**: Did you know whether Baron Grant was consulted in connection with the promotion or formation of the United Company?

Witness said he had never heard the suggestion before.

The **Official Receiver**: Was there not a private telephone wire between Baron Grant's office and the Company's office?

Witness said there was, because he understood that Baron Grant was intimately concerned in the Elmore companies, and that witness's son (Mr. F. L. Rawson) was using every endeavour to make them prosperous and in that way Baron Grant became acquainted with the United Company.

Mr F. L. Rawson explained that the telephone was not between the Company's offices and Baron Grant's offices, but between the Phœnix Trust Company and the United Company.

The **Official Receiver**: Was not Baron Grant's office in the same building as the Phœnix Trust Company's offices?

Witness said he was not aware of it.

Mr. Registrar Hood remarked that the line of the examination was calculated to convey a wrong impression by the introduction of well-known names.

Examined by **Mr. F. L. Rawson**, the **Witness** said that considerable profits were realised during the financial year 1890-91 in connection with the Elmore patents. Steps were taken by the directors to ascertain the value of the Epstein securities, the works committee having gone thoroughly into the value of the patents with the co-operation of their electricians. The opinion of the best patent agents as to the value, and the opinion of three or four eminent counsel as to their validity, had been obtained Witness was satisfied as to the profitable use of the invention and the prospects of the Epstein Company. Special reports were made by the managing director as to the value of the Phœnix Trust shares, and the Board was satisfied with them. He could not remember whether any special valuation was made of the Elmore securities in November, 1891.

The **Official Receiver** intimated that there had never been any suggestion that the shares had not been carefully valued.

The **Witness** further said he fully recognised the fact that Mr. H. G. Rawson had made great self-sacrifices in the interests of the Company, and the Board often reproached themselves for having allowed him to do so. When the sum of £28,000 was advanced to Mr. F. L Rawson it was anticipated that he would wipe out the debt by the amount he received from the liquidation of the old company.

Mr. F. L. Rawson here stated that the notes which he had made of the evidence given during the previous sittings of the enquiry had, to employ a term used by the Official Receiver in the early part of the proceedings, been "spirited away." He applied that he might have an opportunity of reading through the transcript of the shorthand notes.

The **Registrar** granted the application

Sir Rawson Rawson was further examined by Mr. Pilling, and stated that the directors had the option of rescinding their contract to purchase the Kidsgrove works in the event of their not being satisfied with the bargain. So far as he was aware, no steps were taken by the Board to be relieved of the contract after there was found to be a loss on the business He did not know that the directors would have been desirous of disposing of the Kidsgrove works, because they were advised by their general manager (Mr. North) that they were capable of producing a profit of £6,000 or £8,000 per annum.

Mr Pilling: How many members of your family, besides yourself, were connected with the administration of the affairs of the Company?

Witness: When the United Company was formed it took over the limited Company with some of its servants and two of my sons.

Further examined, **Witness** said that his son, Mr. H. Rawson, was invited to attend the board meetings and give the directors the benefit of his legal knowledge, as Mr. Pope Q C., intimated that, owing to the great pressure upon his time, he could not give so much attention to the affairs of the Company. Mr. H Rawson had, as a barrister, advised the board on legal points, and also on other matters.

Mr. Pilling: Did he receive any fees?

Witness: Oh! that was settled by Mr. Pope.

By **Mr. H. G Rawson**: He knew nothing of the affairs of the old company and its subsidiaries, because he had never been connected with them in any way. He saw all the documents relating to the formation of the new company, and made general enquiry into the facts. He consulted Sir Albert Cappel, one of the directors who retired before allotment, and was informed that that gentleman did not wish to continue as a director because he was of opinion that sufficient capital, which he put at £200,000, had not been subscribed. Eventually that sum was reached Sir John Coode had also expressed his opinion to witness that the business was a good and sound one. He satisfied himself that all the statements in the prospectus were correct. If it had been suggested that the directors gave little consideration to the industrial branch, but had devoted their energies to the financial side of the business the suggestion was unfounded. The board always did their utmost to foster the industrial business and it was absolutely contrary to the fact that the directors had neglected it. He had incurred liabilities as guarantor on behalf of the Company to the extent of £8,000 or £10 000. During the past 18 months the directors had practically received no fees, and during the last year they had attended three or four times a week for six or seven hours *per diem*. The managing director had received about £13,000 from the Company, which he immediately reinvested in preference shares of the Company. The Board had throughout acted upon the advice of their solicitors, and, so far as he was aware, they had never declined to follow that advice on any important point. Careful consideration had been given to the suggestions of the auditors and witness had no reason to think that they were not satisfied upon any question which arose. To the best of his belief every balance sheet that he had anything to do with had been fairly and correctly drawn, and, to his knowledge, the value of the assets was never exaggerated. In his opinion the directors were justified in every case in paying the dividends which were declared. The circulars and prospectuses were accurate and not misleading, and great care had been exercised to make sure that the statements contained in them were not exaggerated.

Mr. F. L. Rawson, the late managing director of the Company, was next examined. He stated, in reply to the Official Receiver, that he was not a considerable holder of shares in the limited Company. The joint interest of the late Mr. Woodhouse and himself did not, he thought, represent more than from £10,000 to £16,000. He could not say whether he had any interest in the shares standing in the name of Mr. Woodhouse in the Manufacturing Company. He appeared to be a holder of 261 shares in the Supply Company. As to 108 shares in the Contract Company, he believed that he held those for Woodhouse and Rawson, Limited. The business of Woodhouse and Rawson was started in 1881, and five or six years later the concern was undoubtedly solvent. He absolutely dissented from the evidence which had been given to the Official Receiver to the contrary.

The **Official Receiver**: A balance-sheet of the Manufacturing Company, dated June 30, 1890, shows there was a deficiency of £44,000, even taking the goodwill at £37,265.

TUESDAY.

The **Official Receiver**, at the resumption of the proceedings on Tuesday, stated with regard to a remark made by his Honour on the last occasion as to the introduction of well-known City names into the enquiry, that he had correspondence in his possession which would prove that Baron Grant was consulted in connection with the promotion of the United Company.

Mr. Registrar Hood intimated that he did not wish to restrict the examination in any way which might be considered necessary by the Official Receiver.

Mr. F. L Rawson. the managing director of the Company, was recalled and further examined by the Official Receiver. He stated that he considered the report made by the auditors on the position of the Supply Company in October, 1838, was satisfactory. From the report it appeared that the Company had made a loss during every year of its existence, but witness asserted that the amount of such loss was being gradually diminished, and he was of opinion

Digitized by Google

that the Company would ultimately prove successful. The partnership of Woodhouse and Rawson guaranteed the book debts taken over by the limited Company, and, so far as he was aware, the whole of the debts had been paid. The Woodhouse and Rawson Manufacturing Company, Limited, was liable at the date of the formation of the United Company to the limited Company for £22,000. The whole of this amount had been discharged in cash and shares. The accounts of the Electric Contract and Maintenance Company at June, 1889, showed a loss of £3,430. The amount of the loss had steadily decreased; but the business was a new one, and, it being of a special nature, a loss would be made until the corner was turned and the Company improved its position. The amount paid for the goodwill of that business was £5,000.

The **Official Receiver**: Do you seriously suggest that a business which has been conducted at a loss throughout can possess any goodwill?

Witness said he did if the loss was diminishing. The prospects of the Company were very favourable, and there was ample ground for considering the goodwill to be valuable.

The **Official Receiver**: Who was the financial adviser who assisted in the promotion of the Company?

Witness said that in the early days he was advised by Baron Grant, who was anxious that certain electrical concerns in which he had a hand should be included in the amalgamation scheme. Baron Grant had nothing to do with the actual promotion of the Company, but witness had taken his advice very frequently. He was advised by his solicitors that Baron Grant was a man capable of giving excellent advice on the promotion of the Company. When several articles appeared in the papers commenting upon the Company witness was advised to take no notice of them. Baron Grant was very particular in respect of the information which he required, and he was a man of great experience. The witness said that he went to the National Financial Corporation for the advice—he was afraid that he had fallen into the bad ways of the Official Receiver in using the name of Baron Grant instead of the corporation. The baron was practically the corporation. Witness consulted Baron Grant with reference to the paragraphs appearing in the Press, because his mode of dealing with those matters was A 1, whereas that of witness was below zero The directors of the United Company went thoroughly into the businesses which Baron Grant had in hand, and decided not to include them in the amalgamation scheme. The baron felt that he had been rather badly treated, and ultimately a fee was given him of £5,000 as consideration for his services. Witness, feeling that the fee was not large enough, agreed to give the baron 10 per cent. upon anything which might be realised from the founders' shares to which witness was entitled in the limited Company.

By the **Registrar**: As a matter of fact the latter had not been received, and the baron only got the £5,000 for his services. The baron had no interest in the limited Company.

The **Official Receiver**: Any money which the baron received was in consideration of his friendly advice.

Witness: Not friendly advice; advising in that way was his business.

The **Witness**, continuing, said that the Phœnix Trust was mainly composed of Baron Grant, the National Financial Corporation (of which the baron was the moving spirit), witness, and his wife. Witness drafted the prospectus of the United Company. In it the statement appeared that the profits of the business of Woodhouse and Rawson, Limited, for the year ending June 30, 1888, as shown by the audited balance-sheet, amounted to £21,440. Witness desired that the auditor should certify these profits, but he declined to do so, and said that if he allowed his name to appear in any way he would have to refer to his report. Witness never understood that the report of the auditor should have been read with the certificate given. The auditor was satisfied, so far as witness was aware, of the correctness of the valuation of the assets, but as he could not certify the value it was impossible for him to give the usual certificate. The certificate was ultimately given as follows: "We have examined the books of the Company and certify the accounts to be correct in accordance with our report." Their auditor (Mr. Pixley) had the reputation of being one of the most particular accountants in the City, and it was one of his habits to give a report qualifying his certificates.

The **Official Receiver**: Can you point to any paragraph in the prospectus which would lead anyone to understand that the Company would engage in a financial business?

Witness said the prospectus stated that considerable profits had been realised from business introduced by patentees and vendors of processes, to whom advice would be given. The memorandum and articles of association clearly set forth the business which would be conducted by the Company, and it appeared that the financial business was contemplated.

The **Official Receiver** next examined the **Witness** with reference to the valuation upon which the United Company acquired the patents. It appeared that they were valued at £159,000, the Company paying £85,000 for them. Witness denied that the valuation was made at his instigation, but alleged it was taken at the instance of the new directors. He was unable, however, to state which gentleman had consented to act as a director at the time it was made.

The **Official Receiver** remarked that it was very difficult to gather from the valuation what was the actual value of the patents.

Mr. Registrar Hood said he was afraid that was a very common occurrence in connection with valuations.

Witness said that he gave the instructions for the valuation on behalf of the directors *in posse*. He could not say whether Lord Aberdare, Colonel Howard Vincent, or other Directors had been consulted upon the subject. He had taken great pains to impress upon the valuer the fact that the valuation was to be made for the United Company and not the limited Company. Referring to his connection with Baron Grant, witness said that no payment was made to the baron personally, but to the National Financial Corporation, through whom all the negotiations were conducted. He could not give the names of any of the directors besides Sir Rawson Rawson and Mr. Philip Rawson who were aware of his connection with the Phœnix Trust Company in September, 1890. The matter was mentioned at several board meetings.

The **Official Receiver** observed that Mr. Philip Rawson denied all knowledge in the matter.

Mr. H. G. Rawson: What is the relevancy of the whole question?

The **Official Receiver**: To show that one director was making a large profit unknown to the other directors.

Witness asserted that at a meeting in October or November, 1890, he stated to the directors that there was nothing incorrect in his transactions with the Phœnix Trust, and that he would not only give up to the United Company the shares he held, but also the dividends he had received during that year. The directors did not think it necessary for him to do this, and it was not done.

Sir Rawson W. Rawson, recalled, stated that he was aware early in 1890 of his son's connection with, and pecuniary interest in, the Phœnix Trust. His recollection was that the circumstances were reported to the board, and that the attention of the directors was first called to the matter some time in 1891. He was not aware who were the principal persons concerned in the Trust until the present enquiry was instituted.

By **Mr. H. G. Rawson**: The managing director had surrendered 25 out of 50 founders' shares which he held in the Phœnix Trust to the United Company.

Mr. F. L. Rawson, further examined by the **Official Receiver**, stated that in conjunction with Mr. Philip Rawson he was appointed a committee to act in connection with the Company's dealings with the Okonite Company. With the sanction of the directors they applied through nominees for and acquired a considerable number of shares in that Company. By some oversight the authority to purchase those shares was not recorded in the minute-book of the Company. Owing to the insufficiency of capital subscribed, Sir John Coode, Sir Albert Cappel, and Colonel Howard Vincent resigned their seats on the board, and Sir A. Cappel desired to have a circular forwarded to the applicants for shares, informing them that they were entitled to withdraw their applications. In the circular this paragraph was omitted. Witness stated that he was responsible for the circular, but added that he disclaimed all responsibility with regard to the omission.

Mr. Registrar Hood observed that the circular was an important one, and the omission of the particular paragraph would be a matter for comment later on.

Witness further stated that the auditor had advised the directors not to pay a dividend, but that gentleman held rather exaggerated ideas upon the subject.

The enquiry was again adjourned until to-day (Friday).

COMPANIES' MEETINGS.

NATIONAL TELEPHONE COMPANY, LIMITED.

The annual meeting was held on Wednesday at Cannon-street Hotel, Mr. J. Staats Forbes presiding.

In moving the adoption of the report, the **Chairman** pointed out that the accounts were made up to June 30 last, and therefore covered 14 months. The object of this was to make the two meetings which it had been decided to hold each year fit in with the calendar year. For the purpose of comparing the progress they had made in the 12 months ended April 30, 1894, with the previous year, an abstract of accounts had been prepared, which showed that the income accrued in respect of the business of the year was £682,950, against £583,590 in the corresponding period of the previous year, while the working expenses and other charges, excluding debenture interest, had risen from £311,644 in the 12 months ended April 30, 1893, to £344,168 in the 12 months ended April 30, 1894, leaving a balance of £338,781, against £271,945. They had, however, to pay the post office 10 per cent. on all the gross receipts arising from what was called exchange business, which for the past year represented a sum equal to 2½ per cent. on the ordinary shares, or £63,254 Deducting this amount from the £338,781 it brought the net result for the year, which they could appropriate to their own purposes, to £275,526, as compared with £217,725 in the preceding 12 months. Out of the available balance, after paying the final dividends recommended in the report, the Board proposed to transfer £63,429 to the reserve fund, so as to bring it up to £225,000, and to carry forward £1,765 Referring to the capital account he remarked that every additional subscriber necessitated an outlay of about £42, and consequently their capital expenditure, owing to the nature of their business, must continue to grow. It was satisfactory to find, however, that the capital outlay during the past 14 months had proved to be remunerative. After referring to the arrangements which had been carried out for the redemption of the £1,000,000 of 4½ per cent. debenture stock of the Company by its conversion into 3½ per cent. debenture stock, he explained the negotiations with the Post Office in relation to the acquisition of the trunk lines of the Company, and added that as all difficulties in the matter had now been practically overcome, the agreement would shortly be submitted for confirmation to the House of Commons, and he did not anticipate any serious objection being raised to it. In conclusion, he moved the adoption of the report.

Lord Balfour of Burleigh, who seconded the resolution,

Digitized by Google

referred to the complexity and difficulties of the problems to be faced in giving an efficient service to London.

Mr. Galbraith asked what the chairman had to say in reply to the letter written by the Postmaster-General to Mr. Henniker Heaton, M.P., dated the 6th inst., in which Mr. Arnold Morley said: "On the termination of the license in December, 1911, the right of the National Telephone Company to carry on telephone exchange business will cease. All they will have to sell will be their plant, and even this the Government will be under no obligation to buy."

The **Chairman** said that literally the statements contained in the letter were true, but there were some truths which were a good deal qualified by considerations and circumstances. "All they will have to sell will be their plant," was not true in fact. Mr. Arnold Morley when he wrote the letter no doubt believed it was, but he had not considered the fact that a large portion of their business consisted of private wire business. This was a growing quantity, and if they knew their business and played their game properly it would be a hard nut for the Post Office of the day to crack. At the expiration of their lease this business might, perhaps, be worth £200,000 a year, and that would be something to sell. But long before that the Government would have to make up their mind whether they would take over the exchange business or not. Would they, in that case, six or ten years before the moment arrived, embark upon the enormous expenditure necessary to erect the requisite machinery and plant to supersede that already in existence in order to knock down the value of the Company's business? The idea was so reckless that no one could imagine it being entertained by any responsible person. In these circumstances he though the proprietors would do well to discount the words of Mr. Arnold Morley's letter.

After further discussion the resolution was put to the meeting and adopted.

ELMORE'S FRENCH COPPER COMPANY.

A general meeting of this Company was held last week at Winchester House, under the presidency of Mr. J. H. Duncan (the liquidator).

The **Chairman** said the specific object of the meeting was to appoint a board for the resuscitated company; but the shareholders would probably like to hear a few words as to what had been done in reference to the Company. Meetings were held in December, at which a scheme of distribution was approved, but the long vacation ensued, and the order of the court was not drawn up until February 13. The French Company had now got into thorough working order, and by the beginning of next month would be on even an extended scale of working, having laid down considerably increased plant of an important nature. The first six months of the year had been seriously affected by competition, one large company having put down its price to so low a point that this Company did not care to follow. He thought, however, that things in that respect had now come to a head, and that during the remainder of the year their affairs would be carried on smoothly, and at a profit.

Messrs. Duncan, Strettell, and Shurmer were then appointed the Directors, but it was decided to call a further meeting for the purpose of altering the nature of the office to that of trusteeship, and making them trustees.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY.

Directors: James Staats Forbes, Esq. (chairman), Major Samuel Flood Page (deputy-chairman), the Earl of Lichfield, Shelford Bidwell, Esq., F.R.S., Ernest Villiers, Esq.

Eleventh annual report, presented to the shareholders at the annual meeting, held at the Cannon-street Hotel, on the 26th inst.

In accordance with the agreement entered into with the Swan United Electric Light Company, Limited, and unanimously approved by the extraordinary meetings recently held in conformity with the articles of association, the foreign business and assets of the Swan United Company have been taken over as from October 1, 1893, and the accounts now presented include such business and assets in addition to the British business of the Edison and Swan Company itself. After providing for the interest accrued upon the £100,000 debenture stock, there remains a balance of £31,025. 3s. 3d. available for distribution on the share capital. The Board propose out of this balance to pay a dividend on the A shares at the rate of 6 per cent. per annum. An interim dividend at the rate of 5 per cent. per annum having already been distributed in respect of the business of the first half-year ending December, 1893, a further payment. equal to 7 per cent. per annum, in respect of the second half of the financial year will be paid, the balance being carried to the reserve fund. The business of the Company, thus united, has resulted in a credit balance of £34,400. 3s. 3d.; of this £8,836. 19s. was distributed on March 20 last, as an interim payment on the A shares. The Directors recommend a further distribution of £12,371. 14s. 7d. on the A shares, to be distributed in accordance with clause 87 of the articles of association. This, with £3,375 interest on debenture stock, will absorb £24,583. 13s. 7d., leaving £9,816. 9s. 8d., which the Directors have carried to the reserve fund in accordance with clause 89 of the articles of association. The Directors consider the result as satisfactory, and also that the volume of business has increased during the year, in the face of active opposition in the lamp business since the expiration of the Key patent in November last. The diminution of the money value of the sales is entirely due to the serious reduction in the price of the lamp. Mr. J. S. Forbes retires by rotation from the Board, and offers himself for re-election. Messrs. Welton, Jones, and Co., the auditors, offer themselves for re-election.

Mr. John Staats Forbes, who occupied the chair, stated that the meeting was rather an interesting one, as marking a new departure, as it was from October 1 last that the united business came into operation. The report showed that the companies had now been fused completely, and the balance sheet showed the first results of the united concerns. The Company were also now in open competition, owing to the lapse of the patent, with many keen rivals, and it was prudent for them to follow the example of ordinary traders and keep a good deal of information to themselves. It was not expedient to state where their business was, or how the profits were made. The accounts revealed something, but only the general results. The present position of affairs had been anticipated at the general meeting last year, when the speaker had warned them what would be the result of the expiry of the patent. The cost of the patent had largely come back in the shape of dividends. There was a great difference in the prices of lamps comparing 2s. 9d. and 1s.,

Digitized by Google

and at the same time the cost of construction and management did not diminish. They kept a large stock, and that was a protection to the Company, for there were so many gradations of lamps that a complete stock of all kinds was necessary to secure customers. They had had to lay themselves out for this, and consequently had a great advantage over small manufacturers. In fact, the small manufacturer had to lock up so much capital in stock that he could hardly live on the manufacture. The value of their stock on June 30 was £87,768, as compared with £63,349 the previous year, an increase which was partly due to what they had taken over from the other company. Mr. Forbes then ran over the various items in the accounts printed above, and stated that during a portion of the year the Company had been still protected, the amount of the benefit being between £16,000 and £17,000. They were not afraid of competition, notwithstanding the eagerness with which lamps were pressed on the market at the expiry of the patent, and even in anticipation thereof. They had sold about the same number as before, though of course there was a marked reduction in the profits, but they had a character as well as a lamp. The valuation of the stock had been reduced, and stood well within its value, being taken as the cost of production less a discount. Their cost of producing was such that they did not fear competitors and the quality was maintained. What they had to lose by the reduction in price they hoped to make up by future increased sale. They had a good sound commercial business which had a good future before it. It might be prudent further on to apply some of the profits to redemption of capital, but that was not a pressing matter. With respect to their holding in La Compagnie Générale des Lampes Incandescentes they could cease to be partners next year, and it might be better to be free to sell all over Europe than being tied down by the agreement with the foreign company. Mr. Forbes then moved the adoption of the report.

Major S. Flood-Page seconded the motion, which was agreed to.

On the motion of **Mr. Forbes**, seconded by **Major Flood-Page**, it was agreed to declare a dividend on the A shares of the Company, of 2s. 1¾d. per share on the 89,261 ordinary shares, £3 paid; of 3s. 6⅝d. per share on the 5,000 £5 fully paid shares allotted to the Edison Electric Light Company, Limited; and of 3s. 1¾d. per share on the 12,139 £5 fully-paid shares allotted to the Swan United Electric Light Company, Limited; being, together with the interim dividend paid on March 20, 1894, 6 per cent. in respect of the year ended June 30, 1894.

Mr. Forbes stated that steps would be taken to get a quotation as soon as the old company had been wound up and an apportionment of the shares made.

On the motion of **Major Flood Page**, seconded by the **Earl of Lichfield**, Mr. Forbes was re-elected a director. Messrs. Welton, Jones, and Co., were re elected auditors.

DIRECT UNITED STATES CABLE COMPANY, LIMITED.

The thirty-fourth ordinary general meeting was held on Tuesday at Winchester House, Sir John Pender, M.P., presiding.

The **Chairman**, in moving the adoption of the report, said the revenue for the half-year ended June 30 last, after deducting outpayments, amounted in round figures to £34,843, and the working expenses required £18,750, leaving £16,093 as the net profit, making, with the £3,080 brought forward from the previous half-year, a total of £19,173. A final dividend of 2s. per share was proposed, making, with the three interim dividends paid, a total distribution of 2⅝ per cent. for the year, or £31,872. 15s. After transferring £6,000 to the reserve fund account, which now stood at £281,551. 3s. 7d., the balance of £1,031. 17s. 2d. was proposed to be carried forward. The depression prevailing six months ago still existed, but past experience told them that after a storm came a calm, and with a calm fine weather and brighter times. He had no doubt that would prove to be their experience in the Atlantic system.

Mr. E. M. Underdown, Q.C., seconded the resolution, which was adopted.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

The half-yearly meeting of this Company was held on Tuesday at the offices in Old Broad-street. **Admiral Sir George Richards**, who presided, said there was really no business to transact. A dividend of 10 per cent. had been declared for the half-year, or 12s. per share. The Company had done a good deal of work during the half-year, and had every reason to hope that the Directors would be able to give a good report at the end of the year.

COMPANIES' REPORTS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq (chairman), Harrow Weald, Middlesex; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Wyvenhoe Park, near Colchester; S. Barclay Heward, Esq., 96, Ashley-gardens, Westminster; Edwin Tate, Esq., 21, Mincing-lane, London, E.C.

Report of the directors, with abstract of accounts for the half-year ending June 30, 1894, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Wednesday, August 1, 1894, at 3 p.m.

The receipts from all sources, for the past half-year have amounted to £24,294. 17s. 6d., and the cost of working has been £14,990. 3s. 2d., leaving a profit of £9,304. 14s. 4d. Inclusive of the balance brought forward from December 31 last, the net revenue account shows an aggregate total of £10,368. 8s. 2d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £6,295. 17s. 10d. Out of this sum your directors recommend that the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of 1 per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £1,335. 17s. 10d. to be carried forward to the next account. The following table shows the number of passengers, exclusive of season-ticket holders, carried since the opening of the railway in each half-year:

Half-year ended	Number of passengers (exclusive of season ticket holders.)	Receipts (including season tickets).
Dec. 31, 1890 (11 days)	165,000	£1,568 3 9
June 30, 1891	2,412,343	19,403 6 9
Dec. 31, 1891	2,749,055	19,798 16 6
June 30, 1892	2,813,162	20,931 4 2
Dec. 31, 1892	3,117,602	22,002 17 5
June 30, 1893	3,146,656	22,458 6 9
Dec. 31, 1893	3,093,351	22,067 14 10
June 30, 1894	3,383,154	23,564 10 6
Total since the opening of the line	20,880,323	£151,795 0 8

Your Directors have great satisfaction in stating that the increased traffic has been carried punctually, and free from accident of any kind. The closing of the Oval for football militated against the traffic for the first three months of the half-year, but subsequently there has been a satisfactory increase. The actual cost of working the line for the past half-year has been somewhat less than for the corresponding period last year, but your Directors regret that the local rates again show a marked increase. The locomotives, rolling-stock, generating, and other plant have been maintained in thorough working order and repair, as certified by the engineer. The alterations at the City terminus are complete, and the additional accommodation thus obtained is a great convenience, especially on occasions when the traffic is heavy. The parcels office and left luggage room are in operation, and promise to be a remunerative source of revenue. During the half year £8,200 of the terminable mortgage debenture bonds have been paid off and reissued as debenture stock, or preference shares, at a premium. Your Directors have instructed their engineer to make experiments with the view of substituting motors on the train itself in place of the present separate locomotive, with the object of adding an additional coach to each train. Should this change prove practicable, the number of passengers capable of being carried will be considerably augmented.

CONTRACTS FOR ELECTRICAL PLANT.

CONTRACTS OPEN.

York Town (Surrey).—The Lighting Inspectors desire by the 31st inst. tenders for lighting the street lamps for ensuing season—Specifications may be obtained from Mr. George W. Mason, secretary, York Town.

Nelson.—The tenders invited for the wiring and fittings in connection with the new technical school are to be sent in by the 30th inst. Plans and particulars may be obtained on payment of £1. 1s. by applying to Messrs. Holtom and Fox, architects, Dewsbury.

London.—The tenders required by the London County Council for boilers and fittings, steam and exhaust piping, surface condensers, and air-pumps for the station to be erected for the electric lighting of the embankment are to be addressed to the Clerk of the County Council by the 31st inst.

Hull.—The Corporation invite tenders for two steel Cornish boilers, 10ft. 6in. by 5ft. 3in., delivered on their seats in the basement of the Hull Town Hall. Forms of tender and other particulars may be obtained at the borough engineer's office. Tenders are to addressed to the deputy chairman of the Property Committee, and delivered at the town clerk's office not later than August 1.

Great Yarmouth.—Tenders are invited for repairing, painting, distempering, and other work at the School of Art, and for installing the electric light therein. Plans and specifications may be obtained at the office of Mr. J. W. Cockrill, borough surveyor, Town Hall, Great Yarmouth. Tenders, to be separate for the repairing works and electric light installation, are to be delivered at the office of Mr. T. M. Baker, town clerk, by 31st inst.

London.—The London County Council invite by Tuesday next tenders for the supply of engines, dynamos, motors, switchboards, and other electrical appliances required for the electric light installation for the Victoria-embankment and Waterloo and Westminster Bridges. The drawings may be inspected, and specification, bills of quantities, form of tender, and other particulars obtained at the Engineer's Department, County Hall, Spring-gardens, S.W., on payment of £2. Tenders are to be addressed to the Clerk of the London County Council, Spring-gardens, S.W.

Edinburgh.—The Corporation of Edinburgh invite tenders for the following work: Contract No. 13, supply and erection of Willans engines, alternators, etc.; No. 14, switchboard, instruments, and connectors; No. 15 arc lamps; No. 16, Ferranti rectifiers for arc lighting; No. 17, insulated concentric cable. Copies of the specifications can be obtained on application from the resident electrical engineer, City Chambers, Edinburgh. All information will be supplied by Prof. A. B. W. Kennedy, at 14, Old Queen-street, Westminster, S.W. Tenders must be received in Edinburgh not later than 30th inst. for contract No. 15 (arc lamps), or on August 6 for contracts Nos. 13, 14, 16, and 17.

RESULTS OF TENDERS.

Carshalton.—The tender of the Croydon Commercial Gas Company has been accepted, at £3. 2s. 1d. per lamp, for the lighting of this district with gas for 12 months.

Rochdale.—The tender of the Oldham Boiler Works Company, Limited, of Oldham, has been accepted for the supply of two steel Lancashire boilers for the Health Committee of the Corporation.

Maidstone.—Messrs. Laing, Wharton, and Down's tender has been accepted by the Town Council for the installation of the electric light at the technical schools. The amount of the tender is £1,143.

Ayr.—The Electric Lighting Committee of the burgh of Ayr have decided to place the contracts for the plant required for their new electricity works with the undermentioned firms:

Penman and Co., boiler house plant	£1,541
Siemens Bros and Co., Limited, engine-house plant	5,940
J. Fowler and Co., Limited, Leeds, switchboard	437
Callenders Bitumen Company, Limited, cables and culverts	1,842
Swinburne and Co., Limited, transformers and boxes	420
J. Fowler and Co., Limited, arc lamps and posts	476
S. Z. de Ferranti, Limited, meters	590
Carrick and Ritchie, overhead crane	192

BUSINESS NOTES.

Aberystwith.—The terrace at Aberystwith will soon be lighted by electric light.

Edison and Swan Company's Dividend.—The dividend warrants will be posted on August 3.

Exeter.—The new wing of the Museum, now in course of construction, is to be lighted electrically.

Western and Brazilian Telegraph Company.—The receipts for the week ended July 20 were £2,238.

Eccles.—The Electric Lighting Committee of the Town Council are still seeking information on electric lighting matters.

Forfar.—The Town Council have resolved to oppose the application of the Northern Electric Supply Company for electric lighting powers.

Broadstairs (Kent).—The Broadstairs and St. Peter's Local Board intend to oppose the application of the Brush Company for a provisional order.

Coventry.—Out of a loan for £40,000 which the Town Council are advertising for, £20,000 is to be devoted to electric lighting.

Fleetwood.—The Tradesmen's Association have passed a resolution pressing the Commissioners to carry out their electric lighting scheme promptly.

Lavatory Lighting.—The underground lavatory now being erected in Southwark-street for the St. Saviour's Board of Works is to be lighted by electricity.

Coatbridge.—The Town Council have empowered the Lighting Committee to spend £58 by way of experiment in lighting the streets with electric arc lamps.

St. James's and Pall Mall Company.—The share transfer-books of the St. James's and Pall Mall Electric Light Company, Limited, are closed to August 8.

Harrow.—The clerk has reported to the Local Board that a Bill confirming provisional orders regarding electric lighting has passed both Houses of Parliament.

Ipswich.—The lunatic asylum of the Suffolk Joint Committee is to be lighted electrically. The expenditure on the installation is estimated at between £200 and £300.

Clerkenwell.—The Vestry have received a letter from the County of London Electric Lighting Company giving notice that they are about to lay conduits for electric conductors in the parish.

Barnet.—Mr. Potter, of Mr. Joel's firm has written to the Local Board, stating that he hoped shortly to sell the lamp columns in the Board's yard, as he had received a business enquiry about them.

Metropolitan Electric Supply Company, Limited.—Letters of regret for the issue of £150,000 4½ per cent. first mortgage debenture stock have been posted, and allotment letters were posted on Wednesday.

Hackney.—The Vestry of West Hackney have resolved to apply for the necessary faculty for modernising the interior of the church, and also for lighting it by electricity. The proposed work is estimated to cost £2,000.

Fareham.—A noisy public meeting has been held at Fareham, at which a resolution has been passed deprecating the conduct of the Local Board in determing the purchase of the works without consulting competent authorities.

Notice of Removal.—The Edison and Swan United Electric Light Company announce that on and after August 27 the offices will be removed to the new premises, Ediswan-buildings, 36 and 37, Queen-street, Cannon-street, E.C.

New Offices.—The Telegraph Manufacturing Company, Limited, of Helsby, near Warrington, and of 11, Queen Victoria-street, E.C., have opened new offices at 2, Parsonage, Manchester, where stocks are kept of their manufactures.

Westminster Corporation Dividend.—The Board of the Westminster Electric Supply Corporation have declared an interim dividend at the rate of 4 per cent. per annum for the half-year ending June 30 last, payable on September 1 next.

Anglo-American Telegraph Company.—The Directors recommend a quarterly interim dividend of 10s. per cent. on the ordinary stock, carrying forward £1,173. They state that the new cable between Ireland and Newfoundland is in process of being laid.

Spanish Telephone Company, Limited.—This Company has been registered with a capital of £16 000 in £10 shares to acquire from A. Ruffer and Sons all the share capital now issued of and in the Compañia Peninsular di Telefonos for the sum of £32,000.

Dublin.—It appears that on certain property called St. Sepulchre's Estate, and including lands in Earlsfort-terrace and in the vicinity of Adelaide-road, it is proposed to erect houses, with suitable offices and outbuildings, to be lighted by electricity.

"Victor" Metallic Joints.—We are informed that the Admiralty have for the tenth time given the contract for the supply of "Victor" metallic joints, and other asbestos goods for use in the navy, to the United Asbestos Company, Limited, of Dock House, Billiter-street, E.C.

Bedford.—The Bedford Electric Light Company, Limited, have given notice to the Urban Sanitary Authority of their intention to apply for a provisional order to supply electric energy in the borough. The Mayor and others are to confer with Mr. Jessop, the secretary of the company, on the subject.

Shoreditch.—The Electric Lighting Committee of the Vestry have recommended the appointment of Messrs. Kincaid, Waller, and Manville as consulting engineers in connection with the electric lighting scheme, at a commission of 3 per cent. on the amount of the tender accepted on the original specification.

City and South London Railway.—The receipts of the company for the week ended July 22 were £839, against £764 for the corresponding week of 1893, or an increase of £75. The total receipts for the current period of the present half-year amount to £2,600, as against £2,609 in the corresponding period of 1893.

Bournemouth.—The Town Council, in connection with the recent application of the Council asking the electric supply company for estimate of the cost of lighting the winter garden for a lengthened period, have received a letter from the company asking for further particulars, and these the surveyor has been instructed to forward.

E. and E. Taylor, Limited.—This Company has been registered with a capital of £5,000 in £10 shares to acquire and carry on the business of hydraulic and electrical engineers, general iron-founders, and lift and revolving shutter makers, hitherto carried on by E. and E. Taylor at Moorgate-street, E.C., and Brady-street Ironworks, E.

Digitized by Google

Science Master.—A master is required for next term at Queen Mary's High School, Walsall, able to teach all the usual branches of science for the South Kensington and University local examinations. The salary offered is £120, non-resident. Applications, with copies of testimonials, must be sent to the headmaster not later than August 1.

Devonport.—The town clerk read letters to the Town Council at a recent meeting from two electric lighting companies, in which they intimated their intention of applying to Parliament for a provisional order empowering them to introduce the electric light into Devonport. The letters were referred to the Highways and Streets Committee.

Stafford.—It is stated that as a result of recent experiments in the electric decomposition of brine for the production of bleaching powder and other substances, a company is being formed to establish the industry on a commercial basis The promoters are said to be in treaty for the purchase of land adjoining the Stafford Salt Company's new works at Baswich.

J. Mills and Sons —This Company has been registered, with a capital of £25,000, to acquire and carry on the business of W. J. H Ryder, now carried on at Newcastle, Walker Gate, and elsewhere, under the style of John Mills and Sons, and to continue the trades of brass founders and finishers, coppersmiths, metallurgists, and electrical and mechanical engineers.

Tottenham.— The General Purposes Committee have recommended the Board to decline to give consent to the application of the Tottenham and Edmonton Electric Light and Power Company for a provisional order to light part of Tottenham by electricity, and have recommended that it be referred to a committee of the Board to apply for a provisional order.

Hull.—Mr. A H. Gibbings has reported to the Electric Lighting Committee of the Town Council, stating that the demand on the central station will probably be greater this year than the supply. He consequently suggests that engines and dynamos for further 600 h p. should be procured, at a cost of about £4,500. The question is to receive further consideration. There are now 176 consumers of current.

Liverpool Overhead Railway Company, Limited.—The Directors have resolved to recommend dividends at the rate of 5 per cent. per annum on preference shares and 1 per cent. per annum on the ordinary shares of this Company, less income tax, carrying forward £1,010. The traffic receipts for the week ended 22nd inst. amounted to £1,034, as compared with £740 in the corresponding week of last year.

Newmarket.—It was mentioned to the Local Board on the 16th inst. that the British Electric Light Company, who have obtained a provisional order to enable them to supply the electric light, had written to say they intended applying to the Board of Trade for leave to extend the time for making the necessary deposit until December 23. The Local Board did not deem it necessary to take any action in the matter.

Cardiff —The Free Library Committee met on Tuesday when the question of lighting the new library was considered, and it was decided that a committee should be authorised to consult Mr. Massey as an expert in this work. It was decided to ask the Lighting Committee of the Corporation to include the free library in their inspection with the object of finding the cost of lighting the building by means of electricity.

Mill-Lighting.—Messrs. Bennett and Druce, of Preston, have received instructions from Mr. Edward Barlow, of Radcliffe, for a complete installation of electric light in his mills. The dynamo will be driven off the main mill engine, and about 300 incandescent lamps will be installed. This firm are also installing a gas-engine and dynamo for 250 lights in the premises of the Preston Industrial Co-operative Society's premises.

Wray Electrical Engineering Company, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares, to acquire the goodwill of the business of electrical engineers carried on at Bradford and elsewhere under the style of the Wray Electrical Engineering Company. Messrs. Joseph A. Jessop and Cecil Wray are to be managing directors for a term not exceeding two years. The registered office is at Soho Works, Thornton-road, Bradford.

Church Lighting, etc.—The contract for the electric lighting of Bexhill Church has been placed in the hands of Messrs. Drake and Gorham. The plant will comprise a Crossley "Otto" gas-engine, an Elwell-Parker dynamo, and D.P. battery. The number of lights will be about 50. The entire reconstruction, rewiring, and additions at Mr. Bruno Schroder's installation at Kensington Court has been entrusted to the firm, as well as that of Mr. Harris's house at 18, Montague-square.

Marten Hale and Co.—Mr. F. Marten Hale, whose name will be remembered as the general manager of the late Sphincter Hose and Engineering Company, has secured new patents for an improved method of armouring hoses, and has formed a company, of which he is the managing director, for the purpose of working these patents. The style of the company is F. Marten Hale and Co, Limited, and their registered offices and works are in Emerson-street, Southwark, London, S.E.

Sevenoaks.—A letter has been read at a meeting of the Local Board from the secretary of the Holloway Electricity Supply Company, Limited, giving notice of intended application for a provisional order to supply electricity in the Sevenoaks Local Board district. Having read the letter, the Clerk stated that there was no necessity for immediate action in the matter, as notice of opposition could be given any time before Christmas. It was resolved, therefore, to leave the question in abeyance.

Appointment of Receiver.—The case of the Halifax and Huddersfield Union Banking Company, Limited, against Messrs. Andrews and Preece has come before Mr. Justice Chitty on a motion by the plaintiffs, as debenture-holders of the defendant company, for the appointment of a receiver and manager of the company, which carries on business as electrical engineers at Bradford. Mr. Justice Chitty. the defendant consenting, appointed Mr. James Duff, chartered accountant, Halifax, as receiver and manager of the defendant company's business.

"Medical Battery" Company.—Application was made to Mr. Justice Williams on Wednesday to sanction an arrangement for reconstruction. A new company was to be formed to take over the assets and liabilities of the old company. Mr. Justice Vaughan Williams said he must be satisfied that the business to be carried on was a proper one. and only sanctioned the scheme subject to the memorandum of association being altered so as to provide that electrical treatment and the sale of electrical belts should be controlled by a duly qualified medical assistant.

Llandudno.—The Victoria Palace Company have received permission from the Improvement Commissioners to lay down an inch pipe for supplying gas to a gas engine required for driving a dynamo. Mr. R. Bellis, solicitor to the Llandudno Electric Supply Company, Limited, has written to the Commissioners that it was their intention to apply to the Board of Trade for a provisional order empowering them to supply Llandudno with electricity for private or public purposes. The communication was referred to the Water and Gas Committee without discussion.

Mansion Lighting —Yester House, the seat of the Marquis of Tweeddale, is being fitted throughout with the electric light, water power being used to drive the dynamo. The latter will be situated at the mains, about half a mile distant from the mansion, to which connection will be made by means of an underground cable. There will be a battery of accumulators for maintaining the lights when the dynamo is not running, and altogether some 300 incandescent lamps will be employed. The installation is being carried out by Messrs. A. A. C. Swinton and Co., of Westminster.

Electric Bells.—The Fire Brigade Committee of the London County Council reported on Tuesday that the contract for the maintenance of electric bells belonging to the Brigade will expire early next month, and that they proposed to invite alternative tenders for the maintenance for one or three years As time does not admit of tenderers making themselves acquainted with the condition of the bells and submitting tenders before the recess, the committee have accordingly authorised the chief engineer to arrange for the work to be done by workmen directly employed by the Council until the new contract is entered into.

Collier Audible Telephone Syndicate.—The petition for the compulsory winding-up of this Company was disposed of last week in the Winding-Up Court before Justice Vaughan Williams. The Company was formed for the purpose of working a certain patent, and in March, 1892, entered into agreements by which in effect it transferred its undertaking to another company called the Collier-Marr Telephone Company, subsequently going into voluntary liquidation. The present petitioners, Messrs. W. Shepherd and Sons, were creditors, and on the ground that the voluntary liquidation had been going on for over two years without a satisfactory result, asked for a compulsory order. His Lordship made the order.

Wreck-Raising Company.—The British Wreck-raising and Salvage Company, Limited, has been formed for the purpose of undertaking the salvage of all descriptions of sunken, stranded, and disabled vessels. The capital is £100,000 in 20,000 ordinary shares of £5 each. The prospectus states that the principle of raising sunken vessels by means of pontoons or camels has been shown to be the most practicable and successful that can be adopted. The Company intends to build four camels, which will be fitted with steel masts and derricks capable of lifting the heaviest weights, such as the heavy guns of men-of-war, marine boilers, engines, etc., also with arc and submarine lights for working at night.

Welded Iron and Steel Pipes.—Our attention has been directed by Mr. John Spencer, of the Globe Tube Works, Wednesbury, to his welded iron and steel socket and spigot pipes. These tubes, which are mainly employed for gas and water services, may also be used as conduits for electrical cables and wires, compressed-air and oil main pipe lines. The spigot and socket tubes, which are made from 2in. to 6in. diameter can be fixed by the workmen accustomed to the old lead and yarn joint; and as they can be made about half the weight of cast-iron pipes, and in lengths more than double those now common, the cost of freight and of jointing is thus about half that of the old pipes, and there is no loss by breakage in transit.

Waterloo and City Railway.—The report of the Directors states that the agreement between the Company and the London and South-Western Railway Company, which was sanctioned by the shareholders in February last, has received the approval of the Railway Commissioners, and the Board of Trade have given the necessary certificate for the payment of interest on capital during the construction of the railway, in accordance with the Company's Act of 1893. The contract for the construction of the railway from the Mansion House to Cross-street, Waterloo Station, has been let to responsible contractors, who commenced operations on June 18 last. The terminal stations in the City and at Waterloo will form the subject of separate contracts.

Globe Telegraph and Trust —The net revenue of the Company for the year, after deduction of expenses, amounts to £185,076 13s. 9d., and makes, with the balance of £1,304, 17s. 9d. brought

Digitized by Google

forward, a total of £186,381. 11s. 6d. From this amount there has been distributed the sum of £125,955. 16s. 1d. in interim dividends, leaving an available balance of £60,425. 15s. 5d. The Directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares, and of 3s. 9d. per share on the ordinary shares, making, with the previous distributions, a total dividend for the year of 6 per cent., less income tax, upon the preference, and 4½ per cent. net (against 4½ per cent. for the preceding year) upon the ordinary shares, and carrying forward a balance of £527. 2s. 4d.

Taunton.—The lighting of St. James's Church has just undergone an entire remodelling. The arc lamps which have been in use for the past 7½ years, are now replaced by 55 incandescent lamps, arranged in 12 clusters of four each, suspended from the crown of the arches in the nave and chancel, the remaining seven lamps being arranged as a corona between the choir and the altar and suspended from the chancel roof. The lamps are of 32 c.p. each, and the electroliers are of wrought iron specially designed to suit the architecture of the church. The whole of the arrangements have been planned and carried out by Mr. F. M. Newton, of the Newton Electrical Engineering Works, Rowbarton. The wrought-iron fittings were made by Messrs. Lea, Sons, and Co., Shrewsbury. The power is supplied from the Corporation electric light works by means of a 40 h.p. transformer, made at the Newton works.

Maidstone.—The Electric Lighting Committee of the Local Board have reported as follows: "That they have been for a long time in negotiation with the Electric Construction Company with a view of arranging a transfer of your provisional order to that company, but they have now received a communication from the company which makes it clear to your committee that it will be impossible to come to terms which would be satisfactory to your Board. Your committee therefore recommend that an advertisement be inserted in the leading electrical papers to the effect that no satisfactory arrangement having been come to for transferring the order, your authority are still open to receive and consider offers." Mr. Barker, as chairman of the committee, moved the adoption of the report, and said it was a standing disgrace to think that Maidstone stood still while every other town in England went forward. Mr. Tootell seconded the motion, which was adopted.

Bath.—At a meeting of the Surveying Committee, Alderman Sturges brought forward the recommendation of the Lighting Committee, that the Authority oppose the application by the Bath Electric Light Company to the Board of Trade for a provisional order which would enable them to extend their area of supply to the whole city, and to have entire control over the supply of electric light in the city for 21 years. He said at the end of the present term of seven years under the license the Authority might wish to become the owners of the electric light undertaking. The report was adopted unanimously The Local Government Board have sanctioned the borrowing by the Town Council of £24,650 additional capital for electric lighting. This will enable them to clear off existing liabilities and to make a few extensions. For example, the proposal to light the Cathedral and St. Mary Redcliffe by electricity will be made possible by extending the mains in those directions.

Electric Lighting at Ealing.—The buildings of the Local Board's central electric lighting station at Ealing, which are being erected to the design and under the superintendence of Messrs, Bramwell and Harris, of 5, Great George-street, Westminster, are approaching completion. The contractors for the buildings are Messrs. Wilkinson Bros. The machinery and boiler contracts are held by Messrs. Siemens Bros. and by Messrs. James Watt and Co. respectively, while the mains are being laid by the Callender Bitumen Company. All branches of the work are now so far advanced that the supply of current is expected to commence early in September, and the official opening day has been fixed for the 29th of that month. During the month of October the Local Board propose to hold an electrical exhibition in the Victoria Hall or other suitable place, so that customers may have an opportunity of seeing the uses to which electricity can be put for lighting and other purposes.

Newcastle.—A special committee of the Corporation relative to the municipal authorities undertaking the provision of electricity for the city met on Tuesday. At the last meeting of the Council the sum of £200 was voted for the purpose of employing an expert to give the Council full information as to the cost of producing electric light for the city. Several names of experts were mentioned, and as the city engineer will be in London at the latter end of this week, it was resolved that he should make further enquiries into the matter, and submit his information to a meeting of the above committee to be specially called. The meeting had under further consideration the desirability of approaching the present two electric companies in this city, with a view, if they were disposed to sell, to open negotiations, and this, it was also agreed, should be reported on at the next meeting. The new Masonic Hall to be erected at the Pilgrim-street corner of High Bridge, is to lighted with the electric light.

The New "Hercules" Belt Fastener.—Messrs. Honeywood, Austin, and Co., of 69. St. Thomas's-road, Finsbury Park, N., have sent us a sample of their new "Hercules" belt fastener. This type of fastener is intended for use on any width of band, and for double and cotton belting. It has been designed to meet the requirements for all classes of machinery, including dynamos, and is made of a pliable metal which enables it to give freely on any size pulley, and is particularly suitable for high speeds. The makers claim that these fasteners will effect a saving of expense in bands; that owing to its pliability the fastener will travel quite smoothly over any size of pulley; and that the plates, having ribs on the underside, reduce to a minimum all cutting tendencies and strain that would otherwise come on the holes. It is further claimed that the "Hercules" belt fastener is the only fastener that can be successfully used for both over and under running, and that it will ensure a perfectly steady light on dynamos.

Highland and Agricultural Society.—The annual show of this society is being held at Aberdeen this week. Messrs. Robey and Co., Lincoln, have a 6-h.p patent portable engine driving one of Sayer's patent dynamos to provide electric lighting for the stand. Mr. Alexander Guild, Aberdeen, shows specimens of his "Geob" gas-engines, and a petroleum-engine. Messrs. Crossley Bros. exhibit a large 7-h.p. nominal portable oil-engine, a four-horse oil-engine, and a couple of their Otto gas-engines. Tangyes, Limited, Birmingham, exhibit their Otto gas-engines and a petroleum-engine, which are adapted for driving dynamos. Bickerton's patent "National" gas-engines are shown at work by the National Gas-Engine Company, Ashton-under-Lyne; and the Campbell Gas-Engine Company, Halifax, have in operation several of their oil and gas engines. "Trusty" oil-engines are shown by Messrs. Weyman and Hitchcock, Guildford. Messrs. Robert Stephenson and Co., Newcastle-on-Tyne, exhibit a "Rocket" oil-engine.

Recovery of Gold.—Mr. Justice Romer is hearing in the Chancery Division the action brought by the Cassell Gold Extracting Company, Limited, against the Cyanide Gold Recovery Syndicate, Limited. The plaintiffs are the registered owners of letters patent, granted in 1887 to Messrs. McArthur and Forrest for "improvements in obtaining gold and silver ores and other compounds." This patented process is said to have been largely used. The defendants' process, which is alleged to have infringed the plaintiffs' patent, consists in treating the powdered ore or compound with a solution containing cyanogen, or a cyanide, or a cyanogen-yielding substance, and that is said to be substantially identical with the process covered by the plaintiffs' specification. The defendants deny the allegation of infringement, claiming that under their system the recovery of gold is effected not by the dissolving action of cyanide of potassium, but by something which has not before been employed—namely, electrical action. It is further contended that having regard to the state of public knowledge at the date of the plaintiffs' specification, the patent is bad for want of novelty.

Chili Telephone Company, Limited.—The report for the year ending March 31 states that the small addition to the tariff made towards the close of 1893 caused some subscribers to withdraw, but others have taken their places, so that the aggregate in all centres was 3,987 at the end of the period under review, or only 37 less than at the beginning of the 12 months. By this increase of rates the revenue has been augmented, notwithstanding the smaller number of subscribers, by 55,527dol., the total income being 504,188dol. against 448,661dol. for the previous year. The further depreciation in the sterling value of the currency in which the Company is paid—from 18d. per dollar to about 14d.—has, however, destroyed all benefit from this increase of revenue. It has also increased the outgoings—many more dollars having to be given for the same services—hence the net income was 179,652dol, against 184,673dol., a decrease of 5,021dol. In sterling the diminution of net income is more marked, being at 13 96d. per dollar £10,448, against at 18d. £13,850, or £3 402 down. From this sum of £10 448 are deducted the interest on debentures and other expenditure in London, amounting to £4,943, which varies little from the aggregate of similar items in the previous year. The loss by the reduction of exchange in the sterling value of the liquid assets and liabilities in Chili amounted to £1,979, being less by £1,616. The net profit of the whole business was £3,528, as compared with £5,393, a diminution of £1,865. This net profit of £3,528 has been added to the reserve fund. An ordinary general meeting of the Company will be held at Winchester House on Tuesday next, at 11.30 in the forenoon, for the purpose of receiving the report of the directors and statement of accounts.

Arundel.—The Duke of Norfolk is rebuilding Arundel Castle, which is to be lighted electrically. The supply station has been erected in the New-road, at the top of Poor House-hill, near the entrance to the castle gardens. The building has a total frontage of 92ft., with a depth of 48ft., and is 36ft. high. It comprises boiler-house, engine room, accumulator-room, and fitting shop. In the boiler-house, which is 45ft. by 31ft., are three Galloway steel boilers, 18ft. long by 6ft. 6in. diameter. The engine-house is 36ft. by 24ft. There are three 90-h.p. vertical inverted compound steam-engines, and to each is coupled direct a specially compounded self-regulating six-pole dynamo, capable of working up to 400 amperes. The accumulator-room is 31ft. long and 18ft. wide, and contains two sets of storage batteries, each consisting of 62 cells, and together capable of feeding 260 lamps of 16 c.p. for 10 hours. Low-tension current is employed. The current is led to the castle by two pairs of cables. When the lighting of the castle by electricity was first considered, each contractor was asked to propose his own plan for the most effective internal service. The contractors were called upon to present their own schemes for internal lighting, and to stand or fall by them. When all the plans had been received they were entrusted to Mr. W. H. Preece, and his award was accepted. The building and the general arrangements of the plant have been carried out according to the designs of Mr. A. F. Phillips, C.E., of 31, Great George-street, Westminster, Mr. Gisbert Kapp, of 31, Parliament-street, acting as consulting electrical engineer. Mr. A. Bard, C.E., has acted as the resident engineer. The contractors for the build-

Digitized by Google

ings were Messrs. Read, Blight, and Co. The whole machinery and electrical plant has been supplied and fixed by the Brush Electrical Engineering Company, Limited, London, under the superintendence of their engineer, Mr. W. Geipel, who has also laid the cables and carried out the wiring of the castle. Mr. J. E Sayers has been in charge of the electrical section, and Mr. J. W Donnet in charge of the mechanical department at the generating station.

PROVISIONAL PATENTS, 1894.

JULY 16.

13652. **Improvements in electric switches.** Charles Esson, Montpelier House, Blackheath, London.

13700. **Improvements in telephone switchboard mechanism.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.)

13706. **An improved shade for electric lighting and like purposes.** Albert Henry Entwistle, Henry Joseph Stephens, and Arthur Dubber, 97, Newgate-street, London.

JULY 17.

13728. **A combined pole and lamp-post for supporting overhead wires or cables for electric tramways or railways, telegraph, telephone, and other wires or cables.** Alfred Dickinson, Birmingham-road, Darlaston.

13747. **An improved electrical coupling or terminal.** William Henry Stevenson, 61, Vicarage-road, Willesden, London.

13749. **Improvements in electric signalling apparatus.** Charles Arthur Allison 52, Chancery-lane, London. (The Standard Electric Signal Company, United States) (Complete specification.)

13750. **Improvements in electric signalling apparatus.** Charles Arthur Allison, 52, Chancery-lane, London. (The Standard Electric Signal Company, United States.) (Complete specification.)

13751. **Improvements in electric signalling apparatus.** Charles Arthur Allison, 52, Chancery-lane, London. (The Standard Electric Signal Company, United States) (Complete specification.)

13756. **Improvements in or connected with electrolytic cells and diaphragms therefor.** Charles Nelson Waite, 47, Lincoln's-inn-fields, London. (Complete specification.)

13762. **Improvements in and relating to electric railways.** Charles Daniel Jenney, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13765. **Improvements in and relating to electric railways.** Edward Hibberd Johnson and Robert Lundell, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13771. **Improvements in and relating to electric railways.** Eduard Lachmann, 45, Southampton-buildings, Chancery-lane, London.

13791. **Improvements in or appertaining to incandescent electric lamps.** William Lloyd Wynn Williams and George Herbert Morgan, 6, Lord-street, Liverpool.

13794. **Improvements in electric conduits and conductors therefor.** John Washington Eisenhuth, Rudolph Herman, and Emile Marie Herman, 6, Lord-street, Liverpool. (Complete specification.)

JULY 18.

13836. **Improvements in apparatus employed in the evolution and collection of hydrogen and oxygen gases by electrolysis.** Charles John Yarnold, 64, Upper Tulse-hill, Brixton, London.

13871. **Improvements in or relating to electrical transformers or converters.** James Anderson Kelman, sen, Pinners Hall, Great Winchester-street, London. (James Anderson Kelman, jun., United States.)

13872. **Improvements in and relating to electric railways.** Gustave Vermeire, 45, Southampton-buildings, Chancery-lane, London.

JULY 19.

13900. **An improvements in multiplex telephony.** Abner Mulholland Rosebrugh, 107, Mutual-street, Toronto, Canada. (Date applied for under Patents, etc., Act, 1883, sec. 103, January 6, 1894, being date of application in United States.)

13903. **Improvements in magnetic lock or apparatus for opening the locks of safety lamps by magnets only.** Charles Ellah Stallybrass, 4, Dock-chambers, Cardiff. (Complete specification.)

JULY 20.

13983. **Improvements in apparatus for driving air propelling and exhausting ventilators electrically.** Joseph Wad dington, 8, Quality-court, Chancery-lane, London.

13993. **New or improved electric light regulator.** Augustus Hamilton Johnston, 33, Chancery-lane, London

13995. **Improvements in or relating to electric railways.** William Phillips Thompson, 6, Lord-street, Liverpool. (James Francis McLaughlin, United States.) (Complete specification.)

JULY 21.

14029. **Improvements in prepayment mechanism applicable to gas, electricity, and like meters.** Stephen Simpson, Albert Works, Mansfield, Notts.

14065. **Improved electric fuse head for use in blasting.** William Albert Malson, Tom Malson, Sidney Richard Malson, and Emmanuel Smith, 54, Fleet-street, London.

14069. **Improvements in electrical governors for water-wheels.** Carl Schurz English, 18, Buckingham-street, Strand, London. (Date applied for under Patents, etc, Act, 1883, sec. 103, December 23, 1893, being date of application in United States.) (Complete specification.)

14080. **Improvements in incandescent electric lamps.** George Frederick Redfern, 4, South-street, Finsbury, London. (Carl Schwabe, Germany.)

SPECIFICATIONS PUBLISHED.

1893.

6677. **Railway electrical signalling devices.** Grimes.

13779. **Telephone circuits.** Möller.

14000. **Electricity meters.** De Ferranti.

14003. **Electric circuit closing devices.** Goldston.

14481. **Ammeters and voltmeters.** Moy.

14997. **Electric contacts for telegraphic vibrators.** Edwards. (La Cour.)

15074 **Electric coupling.** Cooper and others.

15355. **Electric battery.** Pyne and Thompson.

1894.

5253. **Producing and utilising electricity.** Wise. (Lewis.)

5254. **Producing and utilising electricity.** Wise. (Lewis.)

6482. **Telephonic systems.** Moreau and Munier.

8599 **Electric arc lamps.** McKeown.

9362. **Electric alarm clocks.** Bromhead. (Beuner.)

9968 **Arresting motion of electrically-propelled mechanisms.** Sperry.

10045. **Electric motors, etc.** Ormsby and Banister.

10169. **Secondary battery plates.** Blot.

NOTES.

Burgdorf (Hanover).—It is proposed to establish a central electric light station here.

Telephony at Bruchsal.—Good progress is being made in establishing a telephone system here.

British Association.—The annual meeting of the association commences at Oxford on Wednesday next.

Electric Lighting in Magdeburg.—Tenders are invited by the Municipality for the electric lighting of the town. They are to be sent in by October 31.

Simbach-on-the-Inn.—Mr. Hellmansberger, rope-maker, intends to introduce the electric light here. The work will be carried out by Mr. Leitl, of Neuölting.

Electric Traction at Belgrade.—An electric tramway, about 3½ miles in length, constructed by a French company, has been opened between Belgrade and Topscheider.

Electric Transmission at Remscheid. — The Electric Street Tramway Company are experimentally putting up an electric motor in a local works for driving machinery.

Electric Lighting at Arad.—The local authorities of this Hungarian town have approved of an agreement with Messrs. Ganz and Co. for the introduction of the electric light.

Nice.—The electric lighting of Nice is, to a certain extent, at last an accomplished fact. It is at present restricted to the Place Masséna, Avenue de la Gare, and adjacent streets.

Electric Traction at Gmunden.—A 90 years' concession has been given by the Austrian Government to Messrs. Stern and Hafferl, of Vienna, for an electric railway at Gmunden.

Electricity at Mannheim.—Circulars have been addressed to industrial firms by the Municipality in order to ascertain what the probable demand will be for current for light and power purposes.

Hospital-Lighting.—The new fever hospital being erected at Shooter's Hill for the Metropolitan Asylums Board is to be lighted throughout by electricity. The architect is Mr. T. W. Aldwinckle.

Electric Traction in Madrid.—The Madrid Tramway Company have decided to introduce electric traction on their lines according to the plans of the Allgemeine Elektricitäts Gesellschaft of Berlin.

Obituary.—The death is announced of Sir George R. Prescott, Bart. The deceased was chairman of Callender's Bitumen, Telegraph, and Waterproof Company, and a director of the Chelsea Electricity Supply Company.

New Cable.—The Anglo-American Telegraph Company announce the completion of the laying of their new cable between Ireland and Newfoundland. This is the eighth cable this company has laid across the Atlantic.

Report on Dry Cells.—We have received a copy of a report on dry cells of the Obach and E.C.C. types by Prof. A. Jamieson, M.I.C.E., and published by Messrs. Siemens Bros. and Co., Limited. In a future issue we hope again to refer to this report.

Iron and Steel Institute.—The autumn meeting of the Iron and Steel Institute will this year be held in Brussels, under the presidency of Mr. E. Windsor Richards. The Brussels meeting will begin on Monday, August 20, and will end on Friday, August 24.

Periodic Variations of Alternating Currents.—MM. Hess and P. Janet are investigating the registration of periodic variations of alternating currents. Two preliminary notes on the subject have already been presented to the French Academy of Sciences.

Distribution of Electrical Energy by Alternating Currents.—In the article given in our last issue on this subject, a type-written error unfortunately escaped notice in regard to the "units to the £ capital.' The figure given was "1·00." This should be "3·46."

Station-Lighting.—The Midland Railway Company are extending their installation of the electric light at Leicester. For some time their offices in Leicester have been lighted by electricity, and extra plant has recently been laid down with a view of lighting up the goods yard.

Only the Subscriber.—A little storm has arisen in the German press in consequence of the rigorous application of an old regulation which prohibits a subscriber to a telephone exchange from allowing anyone not of his household to use the instrument. The withdrawal of the regulation is being asked for.

Electric Lighting at Graz.—Good progress is being made with the laying of the cables here, and the work in connection with the machinery buildings at the central station in the Steyergasse is also making headway. It is expected that the inner portion of the town will receive current by December 1.

Electric Central Station at Goldberg.—The Municipality of this Silesian town are not disposed to run an electric light station on their own account, and in consequence Messrs. Schuckert and Co. propose to erect a central station for the supply of current for lighting and power purposes.

St. Martin's-le-Grand.—The large building in St. Martin's-le-Grand designed for the Administrative Department of the Post Office, is now so far advanced that it is hoped that the transfer will be made before the New Year. The electricians of the Post Office are now fitting the building with the electric light.

Telegraphy in Asia.—The construction of the telegraph line between Burma and China is being proceeded with. The Bombay, Baroda, and Central India Railway Company has asked for a third telegraph wire on the Godhra-Rutlam from Anand to Rutlam, and for a fourth wire between Bombay and Anand.

Imperial Institute.—A special exhibition of submarine telegraph instruments and appliances, connecting the building with various parts of the world, is now on view. The instruments are shown in operation from 5 p.m. to 10.30 p.m., and models of cables and cable-laying ships, museum of deep-sea curiosities, etc., are also exhibited.

Search-Lights.—The Trinity House, Hull, has given notice that the War Department proposes to experiment with the electric search-light at Paull Battery (on the east shore of the River Humber, and about three miles below Hull) between the hours of 8 p.m. and midnight on certain days from the present time to September 26.

Stellingen-Langenfelde.—The Municipality have been considering the question of lighting the streets electrically for some time, but have not come to a definite conclusion as they are afraid of the expense. They now intend to inspect the central station at Wesselburen, where two twin motors are worked by generator gas.

Heiligenstadt.—The municipal authorities are considering the question of lighting the town electrically. The Dirks Cement Works have announced that they are

Digitized by Google

prepared to lay down a central electric light station. The Municipality have decided to postpone the matter until estimates are obtained as to the probable cost.

Association of Municipal Engineers.—As mentioned in our issue of the 20th ult., the members of this association will hold a meeting in Brussels, commencing on Thursday, the 16th inst. Various visits have been arranged, including the Brussels central electric light station and electric cars, the Antwerp Exhibition, and the Antwerp hydro-electric works.

The Department of Science and Art.—The forty first report of the Department of Science and Art of the Committee of Council on Education has been issued. It is mentioned that the additions to the machinery and inventions division at South Kensington during the past year included Cowper's original writing telegraph and Shallenberger's electric meter.

Western Australia.—The Governor (Sir William Robinson), in opening the Parliament of Western Australia last week, stated that among the objects which the Ministers had in view were the construction of railways and the erection of telegraphs. Among the works to be undertaken were the extension of the telegraph system, and the improvement of lighthouses on the coast.

West Hartlepool.—The tenth annual report of Mr. J. W. Brown, A.M.I.C.E, borough engineer to the Corporation of West Hartlepool, mentions that sanction has been given by the Council to the tramway company for operating the tramcars by electric power on the overhead trolley system, and that a provisional order has been obtained by the Council enabling it to supply electricity.

Laundry and Sanitary Exhibition.—An opportunity for electrical firms to demonstrate the applications of electric lighting and heating will be afforded by the second annual laundry and sanitary exhibition, which wil be held at the Royal Agricultural Hall, N., from Wednesday, November 7, to November 17. Enquiries are to be sent to Messrs. Cordingley and Co., 39 and 40, Shoe-lane, E.C.

Junior Engineering Society.—The summer excursion of this society will be to Cardiff and district, commencing on Saturday, the 18th inst., and terminating on 25th idem. Visits to various works, including the Cardiff electric light works, have been arranged, and the rooms of the South Wales Institute of Engineers, Park-place, will be available for the use of the members during their stay in Cardiff.

Up-to-Date Continental Journalism.—In our issue of July 27 we gave a description of the working of the Chemnitz central electric light station. Since then a German contemporary dated two days later—namely, July 29—calmly informs its readers, in fine Irish bull style, that it may be anticipated that current will be supplied from the station towards the end of last May or the beginning of last June.

Alternating-Current Plant.—As an instance of the rapid development of the use of alternating currents, a French contemporary, *Electricité*, publishes in its issue of 12th ult. a remarkable list of installations carried out on this system during the past few months by Messrs. Brown, Boveri, and Co. These cases, numbering 31, not only concern plant for lighting, but also for the transmission of power for use in various industrial works.

The Waterloo-City Railway.—Work is proceeding on the south side of the River Thames, near Blackfriars Bridge, where piles are being driven into the bed of the river. This pile driving is the commencement of the new underground electric railway between the City and Waterloo. It is intended to sink caissons in the bed of the river at this point, and then to drive a tunnel in two directions—the one going to the Mansion House and the other to Waterloo Station.

Northern Society of Electrical Engineers.—A number of members of this society who have paid a visit to Belgium, have just returned from what has proved to be a most enjoyable and instructive excursion to the Antwerp Exhibition. The members, through the courtesy of the directors, visited the Rue du Chantier station of the Compagnie Hydro-Electrique Anversoise, and some of the members who visited Brussels had the good fortune to inspect the central station in that city.

Detection of Liquor Frauds.—The French Chamber of Deputies has placed at the disposal of the Académie des Sciences the sum of £2,000, which is to be awarded to the inventor who succeeds in devising a simple and sure method of determining fraud practised in the production of alcoholic liquor for human consumption. *Electricité* asks whether the knowledge of electrical conductivity, coupled with that of density, is not a sufficient means if the liquor experimented on is brought to the temperature of melting ice.

The Prevention of Smoke.—The Prefect of the Seine, at the request of the Paris Municipality, has appointed a commission to institute a competition among engineers and inventors for the purpose of bringing to light the best means to be adopted for the prevention of smoke from steam-boilers. At the termination of the competition prizes will be awarded to the best three appliances or systems. The methods to be tested are those for firing boiler furnaces with coal without the emission of smoke.

The Gilgit Road Telegraphs.—The new telegraph offices on Gilgit road are now open. After Mr. Olpherts had inspected and reported on the favourable condition of the line over the Tragbal and Burzil Passes, Gurais was opened, and then Minimarg. The Bunji Astor and Gilgit offices, formerly on the line of communication *viâ* Skardu, will shortly be taken over and worked by members of the Imperial Telegraphs—sent up from Bombay, Calcutta, and othe. places, specially selected to stand the severe winter and to effect the speedy restoration of communication in case it gets interrupted.

Personal.—A few personal friends of Mr. J. Rance, jun., presented to him on Monday a pair of binocular glasses and a pocket compass prior to his leaving for the Transvaal to erect plant for the electrical transmission of power, on behalf of Messrs. Johnson and Phillips, for the Sheba Gold Mining Company. Mr. A. Grundy, late manager and director of Bailey and Grundy (London), Limited, has been appointed electrical engineer to the Battersea Polytechnic Institute. Mr. E. Arnold, the chief engineer of the Oerlikon Works, has been appointed professor of electricity at the Technical High School, Karlsruhe. Mr. W. H. Massey is one of the English jurors at the Antwerp Exhibition.

Electric Lighting at Ballarat.—According to the *Melbourne Age*, arrangements have been completed by the Railway Department with the Ballarat Supply Syndicate for the lighting of the local stations and embankment with electricity. The Government will, it is computed, save about £300 per year by the introduction of the new light as a substitute for gas, which costs about £40 per month. It is understood that the electric light will be in use at the stations before the expiration of three months. Steps will also be taken shortly with the view of illuminating the post and telegraph offices and other public buildings with electricity, and it is probable that the same light will ere

Digitized by Google

long also be introduced at the mechanics' institute. Among those who have promised to accord the Supply Syndicate support are a number of the leading shopkeepers in Sturt-street and other principal thoroughfares in the city.

Laying of New Mains.—The Westminster Electric Supply Corporation intend to lay mains in Smith-square, North-street, Church-street, Tufton-street, and Romney-street; in Berwick-street and St. Leonard-street, and Hindon-street west side; in Moreton-place, Moreton-terrace, and Moreton-street West; on the east side of Strutton-ground and the north side of Great Peter-street; and across South-street. The Kensington and Knightsbridge Electric Lighting Company are about to place underground mains across Cromwell road, and in Gloucester-road and Southwell-gardens. The Notting Hill Electric Lighting Company propose to lay mains and construct street boxes in Phillimore-gardens, Kensington-road, Melbury-road and Holland-park-road, and Pembridge-villas. The St. James and Pall Mall Electric Light Company intend to lay mains in Burlington-gardens, Bond-street, and Clifford-street.

Electrical Engineering Leaflets.—Our contemporary the *Electrical Engineer* of New York has commenced the publication of a series of leaflets on electrical engineering matters, by Prof. E. J. Houston, Ph.D., and Mr. A. E. Kennelly, F.R.A.S. These leaflets, which contain the underlying principles of electricity and magnetism, are issued in three grades: (1) elementary, suited to the study of electrical artisans, wiremen, and to elementary students; (2) intermediate, for students in high schools or colleges, and those beginning the study of electrical engineering; (3) advanced, for students taking technical courses in electrical engineering. The leaflets will be issued in 35 weekly parts, and there will be three leaflets each week—namely, elementary, intermediary, and advanced. Each leaflet consists of eight pages, of small octavo size, illustrated by diagrams and drawings. The first leaflets issued deal with electrical effects, E.M.F., and resistances.

The Douglas Electric Tramway.—The Douglas and Laxey electric tramway has been formally opened to public traffic. A number of ladies and gentlemen (among whom were Mr. A. Bruce and Dr. Farrell, directors of the Isle of Man Tramways and Electric Power Company, Limited; Dr. Hopkinson; Mr. F. Saunderson, C.E., the company's engineer; and Mr. J. Aldworth, manager) travelled from Douglas to Laxey by special car, the distance of eight miles along the cliff being traversed in a little over half an hour. It appears from a statement made by Mr. Nelson that during the week ending July 25 the earnings on the electric tramway were £276, the number of cars running 32, number of miles run 1,698⅔, and number of passengers 22,105. The Government inspection of the line took place on Friday, and Colonel Rich, inspector of railways, and Major Cardew, Government electrician, after travelling over the line and making observations, expressed themselves entirely satisfied with it.

The Pacific Cable Question.—In connection with the recent dispute regarding the reported intention of Great Britain to annex Neckar Island, a barren islet lying under the Tropic of Cancer to the north-west of the Sandwich Islands, an allegation was made, says a Reuter's cablegram from Melbourne, that the intentions of the British Government to annex the island were revealed by the Hon. R. Reid, Victorian Minister of Defence, the Hawaiian Government being thus enabled to forestall the hoisting of the Union Jack. Mr. Reid now denies having revealed the intentions of Great Britain, and states that the entire episode was due to Sir Sandford Fleming, the Canadian engineer, having sent a man to charter a steamer at Honolulu for the purpose of seizing Neckar as a station for the proposed Pacific cable, on the chance that the Home Government would recognise the action. The Hawaiian Government, however, obtained information of this plan, and took steps to prevent its execution.

Electrical Steam Attachment for Launches.—Our attention has been directed to an electrical steam attachment for the propulsion of boats without any alterations in the hull of the boat being rendered necessary. This arrangement has been devised by Mr. E. A. McLachlan, of 55, Brighton-road, Stoke Newington, N., who informs us that by its adoption any existing sailing or rowing boat can be converted into an electric launch without destroying its original character. The stern attachment, which is detachable, is fixed in the place of the ordinary rudder, and the motive power is obtained from accumulators placed under the seats. The large pair-oared rowing skiff, "Richmond Lock," which is equipped with this attachment, can be seen on the Thames. A boat fitted on this method is in operation on the canal at the Chinese water carnival now in full swing at the Agricultural Hall, Islington, where it is carrying passengers. Mr. McLachlan states that the electrical equipment can be supplied to any boat at about one half the cost of an ordinary electric lamp.

Electricity in Mining.—In the course of his presidential address before the British Society of Mining Students, at the annual meeting held on Wednesday in the lecture-hall of the South Wales Institute of Engineers, Park-place, Cardiff, Mr. Frank Brain, M.E., A.M.I.C.E., said that there was no doubt that electricity was the coming power in mines. In the colliery he was connected with they had three electric pumps working underground, and he could speak with confidence of their utility. His company were also putting down a system of underground main tail haulage worked by electricity. Electric coal-cutters were at work in many parts of the country, and scarcely a week passed in which they did not hear of some new electric plant in mines. It was their duty to apply themselves to the discovery and application of every means to the prevention of accidents in mines. Last year there were over 1,000 lives lost by mining accidents, and although this compared favourably with years gone by there was still room for improvement, and they must put into practice what they learned so as to minimise these dangers.

The Nottingham Central Station.—The municipal electricity works at Nottingham will, judging from a hasty inspection a week ago, soon be completed and set in operation. Plans of the buildings have already been reproduced in this journal, together with a preliminary outline of the steam and generating plant. As Mr. Talbot, the electrical engineer to the Corporation, remarked, the Town Council have been fortunate in securing the central site, constituted by the location of the generating station in Wollaton and Talbot streets, close to the Theatre Royal, Market-street, and the Market-place. As far as the generating station is concerned, it may be mentioned that three large Lancashire boilers are already in position, together with the Siemens dynamos and Willans engines, whilst the main switchboard is about completed. A battery of E.P.S. cells now being installed will serve partly as regulators and partly for the public supply when the demand for light is low in the small hours. The distributing mains have already been laid in the compulsory area. The capacity of the station, which is expected to be set in operation in September, in time for Goose Fair, is 10,000 lamps.

City and Guilds of London Institute.—We are glad to learn that the council of this institute has conferred the fellowship of the institute upon

Digitized by Google

Dr. W. E. Sumpner, who, it will be remembered, was awarded the diploma of associate of the institute in 1887, and has since contributed to the advancement of the electrical industry by many original and valuable researches. The council have also conferred the diploma of associate upon the following matriculated students who have this year successfully completed the full course of instruction at the Central Technical College: in applied physics and electrical engineering—M. A. Abrahamson, J. R. J. Bowden, P. J. C. Day, R. A. Fullerton, A. F. Harris, H. C. Leake, A. E. Mayes, W. F. S. Mentheth, M. J. P. O'Gorman, L. L. Robinson, J. Severs, A. K. Taylor, J. A. W. Ward, and R. J. C. Wood; in civil and mechanical engineering—N. Abbott, B. S. Aldis, C. L. Bushell, R. B. Carter, A. O. Cautley, A. C. Hall, A. Hallett, J. H. James, C. Lightfoot, H. G. Lloyd, F. Maeers, B. T. Stubbs, and W. Thomas; and in applied chemistry—A. M. Crighton, A. Marshall, and E. W. S. Schwabe.

Telephony.—A correspondent writing to a Dundee paper from Broughty Ferry says: "I had an interesting experience this afternoon. A friend rang me up by telephone at my house in Broughty Ferry from the Highland Show Yard in Aberdeen, and whilst he was speaking to me he said: 'Wait a minute; I can't hear what you are saying on account of a pipe band which is passing the telephone booth.' I instantly replied: 'I was just hoping you would stop for a minute, as I wanted to hear the band.' The wire was fortunately in very good order to-day, and not only did I hear the pipe music, but I distinctly heard the tramp of the men as they walked past. The tune they were playing was 'The Barren Rocks of Aden,' and it was a most interesting experience to hear pipe music and 'the tramp of armed men' over 150 miles of wire. I have repeatedly before heard by telephone a common eight-day clock striking and piano music at a distance of over 100 miles, and have heard a watch ticking at a distance of about a mile, but I have never until to-day had the pleasure of hearing over the telephone music played in the open air at a distance of considerably over 100 miles."

Iron Ships and Lightning.—Adverting to the "Note" in our last issue concerning a peculiar accident at the Norfolk Navy Yard, the following letter received by Rear-Admiral J. A. Fisher, C.B., from Lord Kelvin will prove interesting. Lord Kelvin says: "With reference to the recent report of a lightning discharge in Norfolk Dockyard, U.S.A., by which two men were killed, it is proved by that accident that to secure against danger to men working under a ship in dry dock there ought to be a thorough metallic connection, by wire rope or otherwise, between several points of the ship's iron, such as bollards, ringbolts, etc., and iron pipes leading to the water outside the dry dock. Similar precautions ought to be taken in respect to the frames of ships on the stocks in the course of building, although we have, so far as I know, never heard of an accident from lightning happening to men at work in the building of ships. An iron ship simply resting on wooden blocks, and without any connection by metal with the water of docks, or river, or sea in the neighbourhood, is certainly dangerous to persons standing on the ground and touching any part of the iron hull during a thunderstorm." It is stated that precautions of this character will be adopted in all the Government dockyards.

Life Buoy with Electric Light.—The Allgemeine Elektricitäts Gesellschaft, of Berlin, send us particulars of a life buoy for use on board ship, which is fitted with an electric lamp so as to be visible at night in the water. The floating apparatus is made of waterproof linen, and is sufficient to bear the weight of three persons in the water, life belts being attached to the buoy. Inside the canvas buoy is a double wooden box containing an accumulator with gelatine material, and it is capable of feeding an incandescent lamp for six hours. The incandescent lamp surmounts the floating buoy in a strong wire frame, and is further protected by an outer strong glass globe. When the apparatus is hanging on board ship, the weight of the lower portion automatically switches off the current, but as soon as the buoy is released and dropped into the water four powerful springs switch the current on. The accumulator will last for two months before requiring to be recharged, so that the apparatus can be employed on board ships where there is no dynamo. The apparatus weighs about a hundredweight, but the accumulator can be made smaller with, of course, a corresponding decrease in the duration of the light. These accumulators with gelatine filling do not suffer from the motion of the ship, or from the fall into the water.

Technical Scholarships.—The Technical Education Board of the London County Council announce that they will be prepared early in October to award not more than five senior county scholarships of the annual value of £60, in addition to the payment of college fees, tenable for three years, and subject to annual renewal. The scholarships are intended to provide the means of obtaining advanced technical training in a university, university college, or technical institute of university rank for students (young men or women) of exceptional ability, who would otherwise find it impossible to secure such training. Candidates must, as a rule, be under 19 years of age on September 1, 1894, but the Board is prepared to consider very special cases in which the candidates are above that age. The scholarships are offered with the view of encouraging the study of science or art, with special reference to industrial requirements, and will be tenable at such institutions giving appropriate instruction within the statutory definition of technical education as may be selected by the scholars and approved by the Board. No candidate will be eligible whose parents enjoy an income from all sources of more than £400 per annum. The county scholarships are awarded under the Technical Instruction Act of 1891, which enables a local authority to provide scholarships for "students ordinarily resident in the district of the local authority." It is therefore essential that candidates should be ordinarily resident within the administrative county of London, including the county of the city of London.

The Transvaal.—With reference to our "Notes" of June 29 and of 27th ult., we learn from the *Elektrotechnischer Anzeiger*, of Berlin, that Messrs. Siemens and Halske are now only waiting for the permission of the Transvaal Government to proceed with the work of establishing a central power station at Witwatersrand. A number of mining companies appear to have agreed to take a portion of their power from the company, and within a circumference which will give the concern vitality. According to the plans which have been drawn up, the station will be erected on the Brakpan Farm, near the coal mines of the same name, and to commence with the station will have a capacity of 3,000 h.p., of which 2,000 h.p. will be delivered to the mines. The district proposed to be served at present covers a distance of 27 miles. The representative of Messrs. Siemens and Halske estimates that the average price on the Randt for 1 h.p. is £56. 10s. per annum, exclusive of interest and depreciation, whereas the company intend to furnish electrically 1 h.p. per year for £45, supplying the electromotors free of charge. There are at present in use on the Randt about 20,000 h.p., so that

Digitized by Google

there is plenty of room for expansion of the station if the 3,000-h.p. installation give good results. It was at first intended to utilise the water power of the Crocodile River, but after further consideration this idea was abandoned as it might have given rise to difficulties in times of drought. The use of water power would have enabled the price per horse-power to have been reduced, but only to a slight extent, as according to a provisional agreement with the colliery owners the coal can be obtained for the station at a low price. The capital of the electric company to be formed is to be £300,000, of which £250,000 are to be devoted to the installation and motors, £25,000 will be paid in shares for the concession and expenses, and £25,000 will be held in reserve.

A Gas View of Electric Lighting.—The statements made by Mr. James M'Gilchrist in his presidential address delivered before the North British Association of Gas Managers in Glasgow last week, show that he is not aware of the progress being made in electric lighting, as the following quotation demonstrates: "Since I last addressed you, in 1881, electric lighting has had a good trial, and were it not for the high cost, it would, I believe, become popular. It is still the rich man's light, and, I fear, can never be anything else. As a gas manufacturer I have had experience of supplying a mansion with gas for illuminating purposes, and of subsequently supplying a gas-engine in the same house to generate electricity—I much prefer the latter occupation, because the account for gas is fully 100 per cent. greater. The first cost and wear and tear on electrical plant is so great that it is impossible to produce the light cheaply. It appears, from calculations that I have made, that the bare cost of storing electricity (without adding manufacturing charges) is equal to the cost of gas delivered on the consumer's premises. Under these circumstances, many and great improvements must be made on electrical plant before electricity can be taken seriously as a rival to gas in point of expense. The Corporation of Glasgow have spent thousands of pounds experimenting on electrical street-lighting, and but a few pounds experimenting with the Welsbach system of lighting with gas. These systems will, I hope, be examined by you while resident in the city. The annual cost of the Welsbach light may be put down at 15s.; the electric light at £20 per lamp." The best answer to the question of cost of the electric light is to be found in the rapid adoption of this illuminant and the preference shown towards it in different parts of the country, and in the erection of new and extension of existing central stations; but where is there much work proceeding in this direction in the case of gas? Moreover, the comparison of a Welsbach light at 15s. per annum with an arc lamp at £20 yearly, is, to say the least, not only amusing, but misleading.

Locomotion in London.—The Public Health and Housing Committee of the London County Council reported on Tuesday that they had had under consideration the best means to be adopted for giving effect to the resolutions passed by the Council, to the effect that the committee should consider and report on the best means of obtaining information on the question of locomotion in London, including railways, tramways, omnibuses, and steamboats, and that, subject to an estimate being submitted to the Council, a sum not exceeding £500 should be expended upon an enquiry on the question of locomotion in London, and that it be referred to the Finance Committee to consider whether this sum should be charged against the £1,000 which the Council is entitled to expend on enquiries under the London County Council's General Powers Act, 1893. In carrying out the above instruction the committee consider that the first step to be taken is the collection of statistics relating to the actual present means of transit, and they think that such statistics, so far as concern omnibuses, tramways, and steamboats, can best be obtained by personal enquiry. The statistical officer estimates that the services of four assistants for eight weeks will be required for the purpose, at a cost of £2. 2s. per week each. Some maps and books would also be required at a cost of about £10, making a total expenditure of about £80. With regard to the question of railways, the committee have been in communication with Mr. J. H. Greathead, and have ascertained that he is willing to report on the whole question of railways in London, and especially as to the cost of constructing railways and the best routes and most reasonable fares, for a fee of 250 guineas. The committee consider the amount asked to be reasonable, and they recommend therefore that the committee be authorised to engage the services of four assistants in the statistical department for a period of eight weeks at £2. 2s. per week each to obtain statistics as to the means of transit provision by omnibuses, tramways, and steamboats in London; and that Mr. Greathead be employed to prepare a report, for the fee of 250 guineas, on the whole question of railways in London.

The Government and Telephony.—The agreement between the Government and the National Telephone Company is not yet ready, but members of the House of Commons continue to keep the matter before Parliament. In this connection Mr. H. S. Foster asked the Postmaster-General a few days ago whether his attention had been called to the fact that the chairman of the National Telephone Company, at the annual meeting of that company, stated that they had come to an agreement with the Post Office, which could now be submitted to the House of Commons for confirmation; whether such agreement had been entered into; and, if so, on what date, and when it would be submitted to the House for confirmation; and whether he could state what opportunity would be afforded to the House for considering the agreement. In reply, Mr. A. Morley stated that an agreement had at last been arrived at between the National Telephone Company and the Post Office, but until the approval of the company had been formally conveyed to him, and the sanction of the Treasury obtained, he would not be in a position to lay the draft agreement on the table of the House. He thought it right to add that some questions connected with companies controlled by the National Company must first be settled, but he had no reason to apprehend that this would involve serious difficulty or delay. In answer to the last paragraph, he pointed out that the agreement did not require the confirmation of Parliament, and he was therefore not aware that any special opportunity for its consideration would be necessary, but the subject was one which could in due course be raised on the telegraph estimates. Mr. Labouchere asked whether the promise given was not that a discussion should be taken before the agreement was signed. Mr. Henniker Heaton asked whether the right hon. gentleman would undertake that the question should not be considered at the end of the session, but should be rather postponed. Mr. A. Morley could not give such an undertaking. The general feeling was that there would be sufficient time to come to a decision. With respect to the question of the member for Northampton, he had distinctly stated that this agreement should be discussed before it was signed. But it was merely a formal confirmation of the agreement signed by the late Government and submitted to the House of Commons at that time. Practically there was no alteration in the agreement, which would be laid on the table in due course.

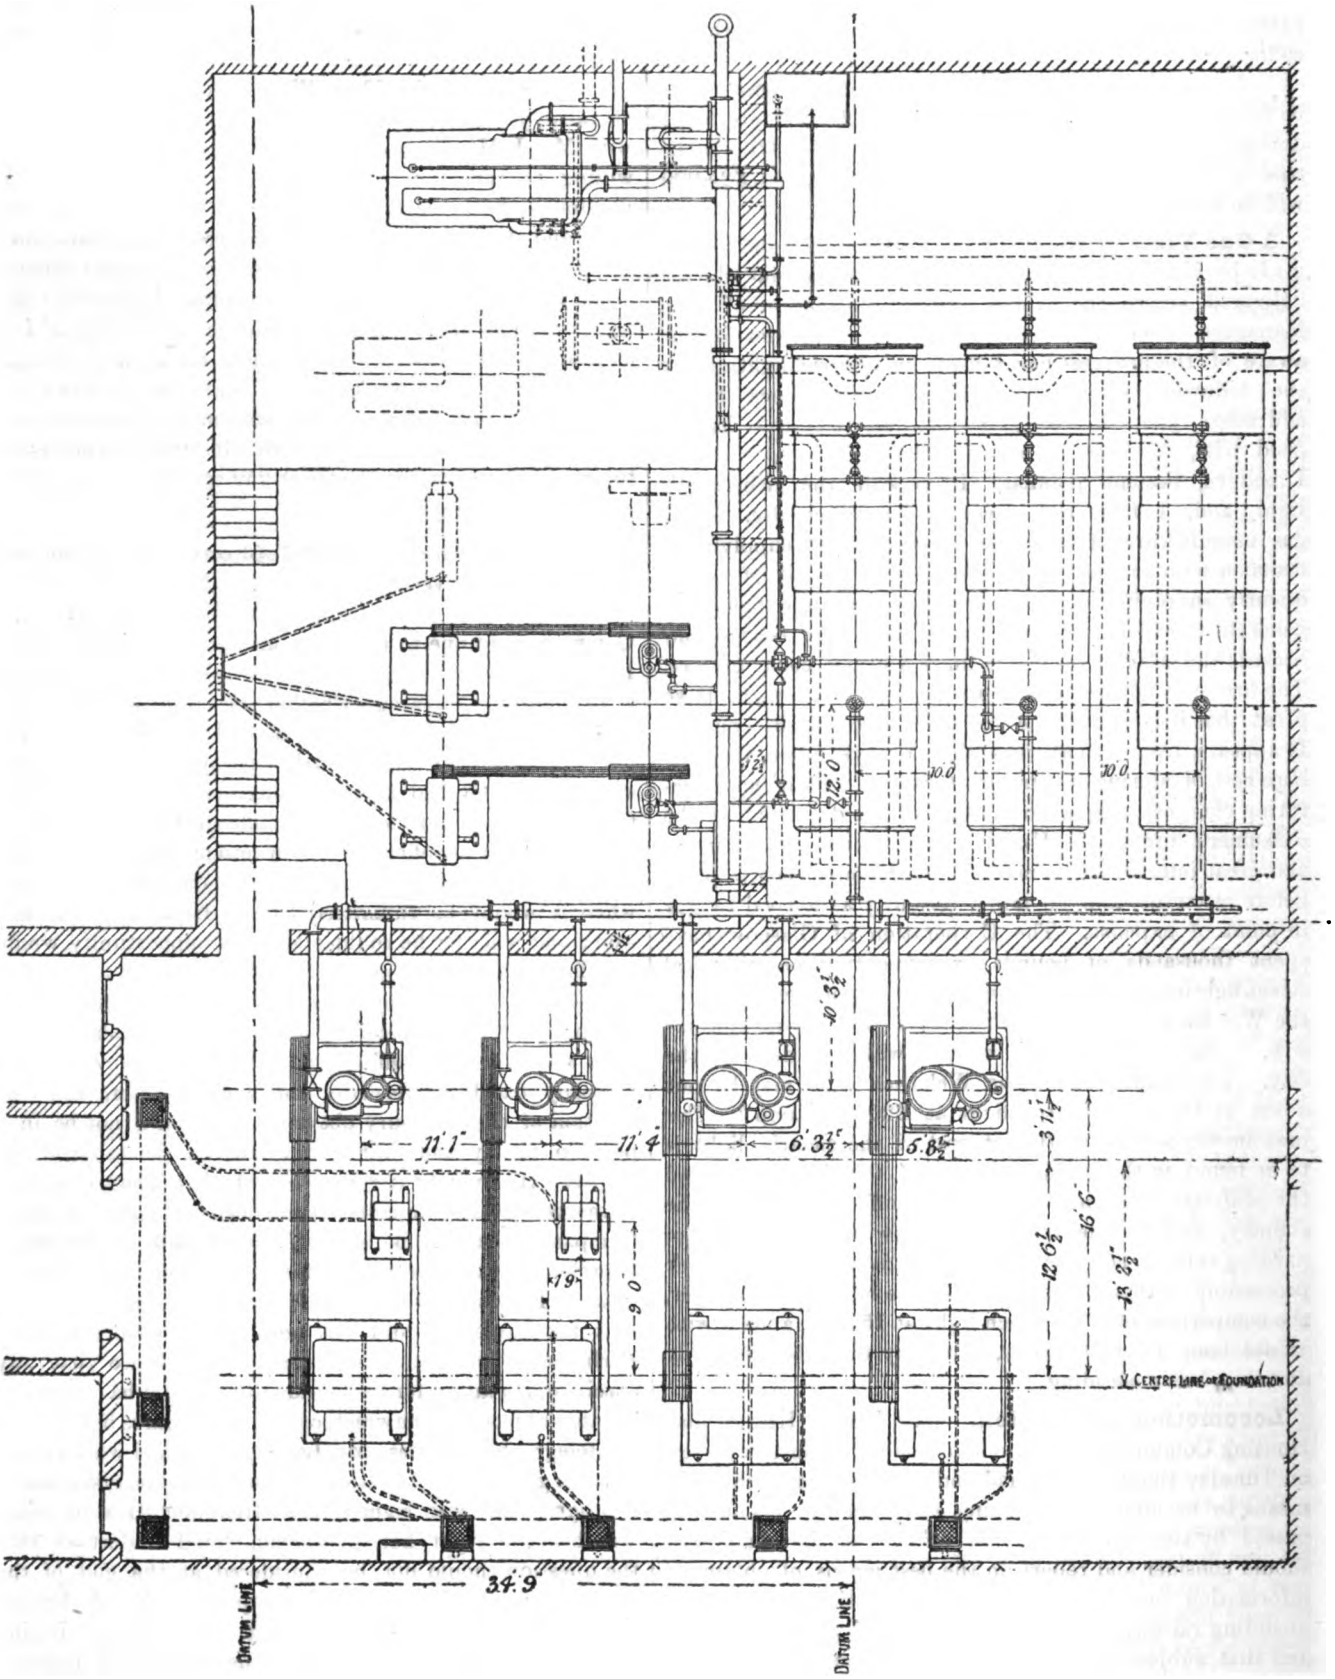
THE MUNICIPAL ELECTRIC LIGHT STATION AT HANLEY.

General Remarks.

A town of the straggling nature which is characteristic of Hanley, well known for its manufactures in china, tiles, and earthenware goods, is precisely the district where one would expect the high-pressure alternating-current system to be adopted for electric lighting; and what is more to the point, this method has been introduced. The Hanley Town Council thoroughly believe in municipalisation, and their belief in electric lighting has taken form in the electricity works which, as we announced in our last issue, were set in operation on Thursday, July 26. Hanley—with its numerous kilns and chimneys belching forth volumes of smoke day and night, its somewhat hilly character, and the few blast furnaces in the outskirts—is not a prepossessing town; but it is one in which the electric light should prove of great value. Mr.



Hanley Central Electric Light Station—General Plan of Main Engine and Alternator House, Arc Light and Condenser Room, and Boiler House.

Joseph Lobley, M.I.C.E. (the borough engineer), is to be congratulated on the able supervision exercised by him in the carrying out of the electricity works, in conjunction with Mr. George Cottam (the electrical engineer to the Corporation), and under the general control of the Electric Lighting Sub-Committee—the chairman of which is Alderman J.

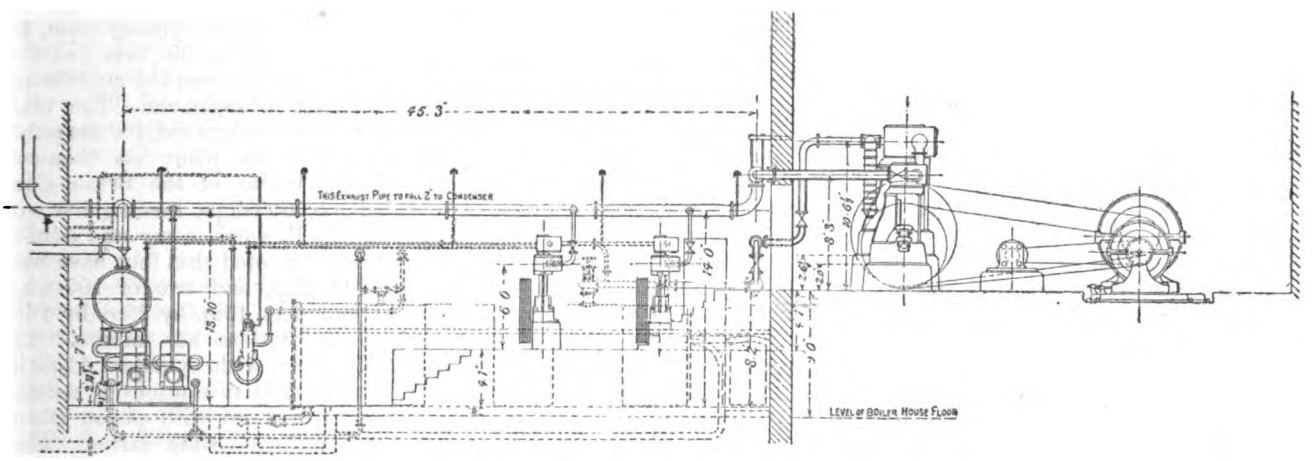
Digitized by Google

Shirley, and the other members are: Councillor A. Wood (vice-chairman), Alderman Hammersley (mayor), Aldermen Charlesworth, Cooke, Hampton, and Ridgway, and Councillors Coates, Huntbach, Palmer, and Turner.

The plans of the station buildings were prepared by Mr. Lobley, whilst the general design and equipment of the station have been carried out by the Brush Electrical Engineering Company, under the control of Mr. W. Geipel (their superintending engineer), assisted by Mr. S. A. Mahood, as resident engineer.

Historical.

The subject of electric lighting first came under the consideration of the Corporation as long ago as in 1882, but the matter dropped. Subsequently Mr. Lobley paid a visit to the United States, and from the experience gained there he came to the conclusion that the alternating-current system was the most suitable for Hanley. This method he recommended the Corporation through the Electric Lighting Committee to adopt, and after investigating existing systems the members of the committee urged the Council to introduce electrical distribution at low pressure, with generation at high pressure by alternating currents. The Corporation, having obtained a provisional order in 1891, decided to adopt the system recommended, and to borrow £21,000 for the purpose of carrying out the undertaking. Tenders were invited for the execution of the work, and in September, 1892, that of the Brush Electrical Engineering Company, at £15,760, was accepted, and a contract was also entered into with Mr. Cornelius Cornes, of London, for the erection of the station buildings. The work of erection of the station was commenced in August 18, 1893, and was practically completed in April last; a partial supply of light began in that month, and regular evening running was started on May 26.



Hanley Central Electric Light Station—Side Elevation of Condenser and Boiler Houses, Arc Light Room, and Main Engine and Alternator House.

Official Opening of the Station.

The formal inauguration of the electricity works took place, as already mentioned, on Thursday of last week, when, at the invitation of the Town Council, a large number of guests assembled at the station.

Alderman J. Shirley mentioned that the number of applications for light had been 70, and that requests for a supply of current for 2,675 lamps for private lighting and for the equivalent of 2,000 lamps for public illumination had been received, the latter including the lighting of the free library, museum, school of art, and public baths, whilst other public buildings are to be similarly illuminated. In other words, 93 per cent. of the total output of the station has already been taken up.

Mr. W. Geipel and Mr. W. M. Mordey followed with some well-chosen remarks, the former urging the necessity o getting a day load, and suggesting the profitable utilisation of alternating-current motors for ventilating and other purposes in the district. Due acknowledgement was made of the courteous treatment meted out to the Brush Company's officials by the Mayor and the Electric Lighting Committee, and of the valuable assistance rendered by Mr. Lobley and Mr. Cottam.

Mr. Edwin J. Hammersley (the mayor) made an appropriate speech. It was mentioned that the British Gaslight Company, which supplies Hanley with gas, had reduced the price of gas per thousand from 3s. 3d. to 3s. in consequence of the Town Council going in for the electric light, and now that the electricity works were completed the company had made a further rebate—namely, to 2s. 9d. per thousand. That reduction, it was stated, was due to anticipated competition of the electric light, and would never have been granted if it had not been for the municipalisation of the electric light undertaking. The Mayor then proceeded to switch on the current to the town lamps.

Subsequent Proceedings.

Subsequently a party of the guests assembled in the Mayor's parlour at the Town Hall, where light refreshments were partaken of and various toasts given and responded to. Some very happy remarks were made by various speakers. Mr. Lobley, for instance, suggested that in order to utilise the current in the daytime a cable should be laid to the sewerage works for the operation of electric motors for pumping purposes, that electric power should be employed for any extensions there necessary, and that the stone-breaker should be operated by electric power. A capital suggestion, Mr. Lobley. The representatives of the electrical Press present, who were obliged to withdraw shortly before eleven, were informed the following day that the proceedings did not terminate until 3 a.m.

The enterprising Corporation of Hanley have dispensed with the services of a consulting engineer in the initiation and completion of the undertaking, and have trusted to the judgment of the Electric Lighting Committee and of the borough engineer for guidance both from a commercial and a technical standpoint. The fact must, however, not be overlooked that considerable assistance has been rendered by Mr. Cottam, and by the Brush Company's staff, one of whom informed our representative that the exclusion of a consulting engineer had resulted in a saving of 30 per cent. on the total capital expenditure.

The Boiler-house.

The buildings forming the generating station (a plan and side elevation of which are annexed) have been erected on the bank of the canal and adjoining Bethesda-road, there being ample space for future extensions, which, taking into consideration the fact that nearly the whole of the present output of the generating plant has been taken up, will soon have to be carried out. The buildings may be divided into the boiler-house, arc light room, and general engine and dynamo house. The peculiar conditions of the site have rendered it necessary to construct the boiler and arc light houses at a much lower level than that of the engine and dynamo room; for instance, a large amount of carbonaceous matter had to be removed from where the boilers have been erected. The boiler-house and the arc light and condenser house are each 50ft. long by 30ft. 4in. wide, whilst the engine and dynamo room is 67ft. 3in. long by 35ft. wide.

The boilers, which were furnished by Mr. J. Thompson, of Ettingshall Boiler Works, Wolverhampton, are of the Lancashire type; they are three in number, each being 28ft. long by 7ft. in diameter. The boilers have an evaporative capacity of about 15,000lb. of water per

Digitized by Google

hour, or, say, 750 h.p. They are made throughout from Siemens mild steel, and built upon the most modern practice. The circular rings of the shells have two rings of rivets, and the longitudinal seams have six lines of rivets; the end plates are also double riveted to the shell angles, and their system is carried out to the connection of the flues to the end plates. The flues contain tubes which are welded at their connection to the flues. The boilers are equipped with high-class fittings, the feed-water connection being in duplicate, and the internal arrangement of tubes for distributing the water is made to the design of the borough electrical engineer. They are constructed for 140lb. working pressure, and the hydraulic test pressure applied was 250lb. per square inch. The maker, it may be mentioned, has had his works equipped with modern tools for the special construction of boilers for heavy pressures. The boilers are fitted with mechanical stokers.

These stokers were supplied by Mr. Thomas Cass, of Hope Foundry, St. George's street, Bolton. The "Cass" smokeless coking stoker is a strong, simple, and durable machine, consisting of a large hopper arranged in front of the boiler, and holding about 10cwt. of slack. The stream of coal falling on the bars is pushed by a pusher plate, and is carried by the action of moving bars under a firebrick arch into the furnace, which ignites the surface of the coal some 5in. thick as it passes through. The moving bars carry the fuel and fire bodily forward along 6ft. of grate bar; then arriving at the end of the bars, the fuel is finally consumed, and the clinkers and ashes fall into a pit at the back, and are there cleaned out twice a day, according to the quantity of ashes. The attendant has only to keep the hoppers full of coal, regulate the feed, and keep clean at the back, whilst the stoker does the rest. The bars are all fitted with steel blocks, as also the tappets which work the bars, so as to prevent wearing away, as would be the case with cast iron. Thus the bars are very durable. The bars run on rollers, which cause the machine to run very easily. Mr. Cass informs us that some hundreds of these stokers have been fitted to the principal mills and works in Lancashire and other places. The machines are driven with a $^{9}/_{16}$ rope, and it is not necessary to drill a single hole in the boiler to apply this type of stoker, this being a great advantage.

The close proximity of the canal allows of the coal being brought to the station at about 7s. 6d. per ton, the coal being taken direct from barges on to a platform, from which it is conveyed by chutes into the stokers. At present only two boilers are required for supplying the necessary steam. The practice of constructing the main steam-piping in the form of a ring has been followed out in this station. The main steam-pipe, which is of wrought iron, 6in. in diameter, is provided with valves which are so arranged that any section may be isolated. The branches to the main engines are 4in. and 3in. The valves are of the parallel slide type, so that when open the steam has a straight passage through. The exhaust piping, which is of cast iron, ranging from 9in. downwards, opens into the condensers or direct to the atmosphere, as may be desired. An automatic relief valve is arranged on the pipe which opens the exhaust to the atmosphere in the event of a stoppage of the condensing plant, whilst a valve is also provided for shutting off the condenser when necessary.

The condensing plant, which is contained in the arc light room, is arranged so that it can be readily extended along with the engines. At present there is one surface condenser of 1,000 square feet cooling surface, and the cooling water is taken from the canal. The air and circulating pumps, which are horizontal, are of the Raworth type, and are fixed on a common bedplate, and are driven by a pair of compound cylinders; whilst a heavy flywheel is provided to enable the steam to be cut off and used expansively. The principal feed pumps are driven from a rocking shaft by the same engine as the air and circulating pumps. The pump rods are attached to blocks which slide in slotted levers, by means of which the stroke may be varied as required. The feed water is taken from the hot-well under the air-pump. In addition, there is a wall feed pump, supplied as a stand-by arranged to pump from the cold-water supply direct or from a tank which is heated by exhaust steam. This pump is equal in capacity to the full power of all the boilers.

Public Lighting.

The arc lighting plant, from which the principal streets are lighted by means of 30 Brush arc lamps arranged on ornamental posts, is operated from machines independently of the private supply, to which reference is made below. It is intended to light the by-streets by incandescent lamps, which are cut in by means of Lobley's patent automatic switch when the arc light circuits are started, so that the whole of the streets are lighted simultaneously by merely switching on at the generating station. The generators comprise two Brush series dynamos, each capable of developing 125,000 watts at eight amperes, running at 900 revolutions per minute. They are 25-light machines, which are rope driven by two vertical tandem type of Raworth compound engines, having cylinders 6in. by 10in. by 8in. stroke, running at 200 revolutions a minute. The engines are fitted with steam stop-valves, continuous lubricating arrangements, grooved flywheels, and Acme governors. The arc light circuit switchboard, which is of polished oak fitted with hook and stirrup connections for two dynamos and one circuit, is also equipped with an ammeter, provision being made on the board for extensions. The arc light main consists of a cable which is highly insulated with vulcanised rubber, protected by prepared tape, compounded and drawn into cast-iron pipes. Geipel's patent telescopic street boxes, constructed entirely of cast iron, are used for these mains.

Main Engine and Alternator Room.

Coming now to the main engine and dynamo room, the dimensions of which are given above, the first point to attract attention is the short drive between the engines and alternators, making a compact arrangement. The plant here is, as will have already been understood, for the public supply of light and the whole of the plant has been constructed at the Loughborough Works of the Brush Company, the total capacity being 5,000 lamps. Dealing first with the engines, which are of the Raworth compound double-acting vertical type, it is to be noted that four have been laid down—two are of 200 i.h.p. and two of 100 i.h.p. The larger engines have cylinders 15in. by 25in. by 16in. stroke, and run at 167 revolutions per minute. The smaller engines, which are fitted with cylinders 11in. by 18in. by 12in. stroke, run at 200 revolutions a minute. The high-pressure cylinders are fitted with piston valves, and the low-pressure with ordinary slide valves. They are controlled by a flywheel governor, acting on the high-pressure valve. The governor is fitted with Raworth's patent adjustment for altering the speed whilst running, and for dividing the load as required between the various machines running in parallel. The low-pressure slide valves are provided with Hackworth gear for varying the cut-off in the low-pressure cylinder whilst running, so that the engines may be operated with the best results for any load.

There are installed four alternators corresponding to the engines, which drive them by means of eight separate cotton ropes. Of the alternators, which are of the well-known Mordey-Victoria type, two are driven at 430 revolutions per minute, and have a capacity of 100 kilowatts each, whilst the other two run at 600 revolutions, and have a capacity of 50 kilowatts each, the pressure being in each case 2,000 volts. The armatures are stationary, as is customary in this type of machine, whilst the field magnets revolve. The lubrication of the bearings is automatic, being effected by means of small pumps, which keep up a constant circulation of oil. These alternators, it will be remembered, work perfectly in parallel irrespective of size.

The exciting plant comprises two Brush-Victoria dynamos, each having an output of 10,000 watts, and capable of exciting all the alternators. These machines are driven by short belts direct from pulleys keyed to the shafts of the two smaller alternators.

We must not omit to mention that the engine and dynamo room is fitted with an overhead hand travelling crane, supplied by a local firm, Messrs. J. Warner and Son, of the Phœnix Foundry, Hanley. This crane, which

Digitized by Google

is capable of lifting a load of 10 tons, has the following motions : (1) longitudinal travelling ; (2) transverse travelling; (3) lifting and lowering. All these motions are effected by hand from below by means of endless chains or ropes. The main longitudinal travelling carriage is constructed of two steel girders, is of sufficient strength to safely carry a load of 10 tons in the centre, and has rails firmly secured to the top for cross travelling carriage. The end frames or carriages for carrying the main girders are of cast iron, and are firmly secured to girders and fitted with large travelling wheels from 20in. to 24in. diameter having double flanges to prevent the crane from running off the rails. It is fitted with spur gearing and shafting connecting each side together, and is provided with two large size chain pulleys, etc., for working longitudinal travelling from either side of the building. The main travelling carriage runs upon iron rails of strong section securely fastened to timber sleepers. The crab and cross travelling carriage are of strong make having sides of cast iron constructed to work inside the main steel girders, and are provided with travelling wheels about 9in. diameter with large chain pulleys. The crab has a strong double-purchase lifting gear ; all the wheels are cast of hematite iron ; the shafts are of best wrought iron, and are fitted with catch gear for sustaining the load ; also powerful brake gear, these with hoisting motions all being worked from below. Messrs. Warner and Son inform us that the crane was erected prior to the completion of the building, and that it was used by the Brush Company to fix the engines and machinery.

The Switchboard Arrangements.

The unit system of switchboard arrangement, introduced by the Brush Electrical Engineering Company, has been carried out in this station. Each exciter has a switchboard arranged for running the exciter in parallel on to the exciter omnibus bars. Platinoid resistances wound on bars of slate with a sliding contact are used in the shunt circuit for regulating the pressure of the exciters, and through them of the whole station. The station voltmeter is placed near these resistances. Each alternator has arranged opposite to it a board equipped with double-pole high-tension fuses and switches for connecting the machine to the station omnibus bars, also an alternate-current ammeter, a voltmeter, and an ammeter on the field circuit. There is also a small plug connecting the alternator to the synchroniser. The synchroniser-board contains two synchronisers and lamps, together with double-pole switches for connecting the synchroniser to the station omnibus bars. It also carries the main station ammeter, and the main station recording meter, which is of the Shallenberger type. After passing through this board from the alternators the omnibus mains proceed to the circuit boards, of which at present there are two. Each is fitted with an ammeter and double-pole high-tension switch and fuse. The method allows of the addition of any number of exciters, alternators, circuits, and their corresponding boards, without interfering with the existing arrangements.

The Distributing System.

The distribution of current is effected by means of low-tension distributing mains at 100 volts pressure from the transformer sub-stations, which are situated at convenient points in the town. There are 14 sub-stations, most of which consist of underground brick chambers, 7ft. long, 4ft. 9in. wide, and 6ft. 6in. deep. One of these transformer stations is erected at the Town Hall, which has not yet been electrically lighted. The distributing mains, which are laid on the Callender solid system, consist of a pair of copper cables of 100 per cent. conductivity, insulated with vulcanised bitumen, and laid in a cast-iron trough, run in solid with refined bitumen. The case is covered by a cast-iron lid laid over the bitumen. The high-pressure feeder mains, which were supplied by Messrs. W. T. Glover and Co., comprise concentric copper cables of 100 per cent. conductivity, highly insulated with vulcanised rubber and tape; they are braided with tarred hemp yarn, and compounded, and are drawn into cast-iron socket pipes, 2in. diameter, coated inside and out with preservative compound. Suitable draw-boxes are, of course, provided at intervals. The high-pressure joints are of the Raworth-Geipel type, which have many advantages over the ordinary vulcanised rubber joints; the joints, being mechanical, are easily made, and can be inspected by merely lifting off the cover, whilst the cable can easily be disconnected for testing purposes. The transformer-chambers contain Mordey Victoria transformers of 18-kilowatt capacity, two or three converters being arranged in each sub-station.

The generating station is lighted by both direct and alternating current lamps, the former being arranged on the town circuit, and the latter on transformers connected across the alternating-current mains. The extent of the lighting so far comprises the compulsory area, and mains have been laid for the supply of current in the following streets : Albion-street, Marsh-street, Newhall-street, Old Hall-street, and all the principal streets and squares within these boundaries; also in Lichfield-street, Vine-street, and other streets on the way to the generating station. As already mentioned, the free library, museum, school of art, and public baths are lighted by electricity, and the other public buildings are to be lighted in the same manner. Several tradesmen's shops and houses have also adopted electrical illumination, and others are about to follow their example. The charge for current is 6d. per unit ; and, altogether, the central station reflects credit on all who have been associated in the bringing of the undertaking to a successful issue.

A NEW ELECTRIC CRANE.

The most suitable type of electric crane for general service would appear still to be a matter of considerable dispute, since each maker or designer claims for his efforts the highest point of economy and efficiency. Probably the true principle underlying these appliances will be found to vary in accordance with the special conditions under which they operate in each case, and no general rule of design can be drawn up for all purposes.

The firm of H. Bollinckx, however, has given considerable time and attention to the study of the question, and has come to the conclusion that certain definite principles may be laid down as applying to the design of electric cranes, at any rate so far as the overhead traveller type is concerned. Whether this conclusion is reliable or sound, must be decided after considering the results of these investigations by Messrs. Bollinckx—who are tolerably well known on the Continent for their engineering work. They conclude, first, that continuous—rather than three-phase or ordinary alternating—currents should be employed for the purpose, if only because lighting and other power transmissions may be effected from the same electric generator, or source of energy. Moreover, they consider that the speed of the crane motors may be varied more easily and with greater precision—a detail of some importance in foundry work when dealing with delicate moulds. The motors may likewise be reversed without employing special precautions or the use of brakes.

In the second place, they consider that a separate motor should be employed for each movement of the overhead crane : a greater mechanical simplicity is thereby attained from the absence of clutches, since the motors run either way indifferently. Thirdly, the current should be collected by means of soft metal contact-pieces easily replaced and renewed : and these should be placed *underneath* the conducting wires, so that the latter may rest freely upon their insulating supports. Since the longitudinal traverse of these cranes usually reaches 100ft. or 200ft., it is advisable to reduce the weight strain in the conductors as much as possible ; and this is best effected by the above plan, because the conductors are not supported from soldered joints as in the case of trolley wires, but simply rest upon the insulators, from which they are raised by the contact-pieces as they pass along.

It is advisable, in the next place, to arrange all the operations which regulate the separate motors, so that as a single lever is moved round in one direction or another it starts, stops, and reverses its respective motor, and regulates the speed as may be desired. Finally, a speed-reducing gear, which consists of a worm and worm wheel,

Digitized by Google

should be used wherever possible, since the entire arrangement may be more easily boxed up and shielded from dust, etc. Moreover, the use of ball bearings to take up the end thrust of the worms becomes practicable, and much friction is thereby saved, especially as the gear is run in an oil bath. These are the chief points brought forward by Messrs. Bollinckx to advocate and explain the special characteristics of the design they now submit.

The annexed illustrations, from the *Revue Industrielle*, show some details of a 15-ton overhead travelling crane constructed on these principles by Messrs. Bollinckx for use in a foundry. The three electric motors employed respectively for longitudinal and horizontal traverses, and for lifting, are all made by the Henrion factory; that marked B drives by means of worm gear and two bevel pinions a cross-shaft, which carries a train of gearing connected with two of the traveller wheels, and so propels it along the gantry rails. At D is the motor for effecting the cross traverse through spur gears that drive an idle shaft carrying other and similar gears connected to the winch carriage. This motor is geared to the first train of spur wheels by means of a compressed leather pinion, so that easy and noiseless working may be secured. The third motor, C, operates the lifting winch by means of worm gear and spur wheels connected to a chain barrel. In this case, and in the first mentioned, the motor is attached to the worm by means of a Raffard flexible coupling. The smaller illustrations—Figs. 2 and 3—show the details of gearing, and also a section through the worm and worm wheel, in which may be seen the arrangement of ball bearings employed, as also the oil bath in which the gear works, and the general system of lubrication.

The longitudinal traverse of this crane is about 65ft. per minute, and the cross traverse 28ft. A speed of 10ft. per minute is attainable in lifting weights up to eight tons, and from 5ft. to 6ft. with a weight not exceeding 15 tons. Within these limits any desired speed may be used, as the revolutions of the motors are variable up to a speed of 1,200 per minute, by using resistances. For lifting heavier weights than those above named a greater speed-reducing gear is provided, as shown at N; this can be thrown in by a lever which moves the worm wheel spindle, H H. The conductors are shown at the side of the crane frame.

(All Rights Reserved.)

(Continued from page 92.)

MAGNETIC UNITS.

§ 48. The unit *magnetic pole*, *m*, is defined in exactly the same manner as the unit quantity of electrostatic electricity was defined in § 39. The analogue to electrostatic inductive capacity is magnetic inductive capacity, generally called magnetic permeability and denoted by μ. Hence the dimensional formula for strength of magnetic pole is

$$[m] = [F . \mu . L^2]^{\frac{1}{2}};$$
$$= [L^{3/2} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}].$$

§ 49. Magnetic *surface density*, σ^1, *intensity of magnetic field*, H, and *magnetic potential*, V, are defined similar to the corresponding quantities in electrostatics in § 40, § 42, and § 43 respectively, and hence their dimensional formulæ are:

$$[\sigma^1] = [L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}];$$
$$[H] = [L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}];$$
$$[V] = [L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}].$$

§ 50. The *moment* of a magnet, M, is the strength of either pole into the distance between the poles. Hence its dimensional formula is

$$[M] = [m . L];$$
$$= [L^{\frac{5}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}].$$

Digitized by Google

If a bar magnet is placed in a uniform field of force, it experiences a couple tending to set it with the lines joining its poles in the direction of the force of the field. When the magnet is so placed that the line joining its poles is at right angles to the direction of the lines of force of the field, the couple is equal to the product of the magnetic moment into the strength of the field. Hence

$$[M] = [G \cdot H^{-1}];$$
$$= [L^2 M T^{-2} \times L^{\frac{1}{2}} M^{-\frac{1}{2}} T \mu^{\frac{1}{2}}];$$
$$= [L^{\frac{5}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}].$$

§ 51. *Intensity of magnetisation*, I, of an uniformly magnetised magnet is measured by its magnetic moment divided by its volume. Hence its dimensional formula is

$$[I] = [L^{\frac{5}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}} \times L^{-3}];$$
$$= [L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}].$$

This is equal to the surface distribution of the magnetism over the ends of the bar, and its dimensional formula is therefore the same as that of magnetic surface density.

§ 52. Magnetic *susceptibility*, κ, is the ratio of the intensity of magnetisation to the magnetising force. Its dimensional formula, therefore, is

$$[\kappa] = L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}} \times L^{\frac{1}{2}} M^{-\frac{1}{2}} T \mu^{\frac{1}{2}}];$$
$$= [\mu].$$

§ 53. *Magnetic induction*, B, is proved to be equal to the resultant of H and $4\pi I$. If the substance be isotropic and has no magnetism except what exists on account of the magnetising force, H, then

$$B = H + 4\pi I;$$
$$= H(I + 4\pi\kappa);$$
$$= H\mu.$$

The dimensional formula for magnetic induction is therefore

$$[B] = [L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}} \times \mu];$$
$$= [L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}],$$

the same as that of intensity of magnetisation.

§ 54. These magnetic quantities may now be put into a tabulated form for convenience of reference.

(To be continued.)

NOTES ON ELECTRIC TRAMWAYS IN THE UNITED STATES AND CANADA.*

BY H. D. WILKINSON, MEMBER.

(Concluded from page 102.)

I have here copies of two Bills which have recently passed the House of Representatives, authorising an extension of tramways in the city of Washington, in which the system of underground conduit I have just described is to be used. The section of the Act incorporating the Washington Traction Company which refers to the system reads as follows: Sec. 2. "That the motor power shall be the underground electric, such as is now in use on the U-street branch of the Rock Creek Railway, on all of its road east of Rock Creek, while the overhead trolley shall be used upon that part of the route north-west of Rock Creek until such territory shall be built up and the District Commissioners shall deem it proper that the wires shall be placed underground." The other Act empowers the Brightwood Railway Company of this city to extend their lines within the city, using the above system. It has been proposed to use synchronous, two-phase, or three-phase motors for tramcars, chiefly with a view to economy in the transmission of energy, but also with the object of avoiding electrolytic troubles. There are advantages to be considered in the use of alternating currents, but it would involve the carrying of line and return close together in the neighbourhood of telephone lines. A tramcar fitted with a three-phase motor, said to be the first one so fitted, was exhibited by Messrs. Siemens and Halske in the electricity building at the World's Fair. The motor was four-pole, of 20 h.p. nominal, but capable of working up to 60 h.p. at 500 to 600 volts and 1,400 revolutions. The reduction gear was enclosed in oil.

I now come to some points in power house plant. Most of the stations I visited had large cross or tandem compound horizontal condensing engines, the average units being of 500 h.p., driving 200-kilowatt generators by belts. These were usually compound machines, to give 500 volts on open circuit to 550 on full load, and had the intermediate connection taken from the brushes to the switchboard for coupling machines in parallel. In allowing for "drop" a good deal depends upon the site of the power house. In the heart of a city, where there are a large number of pedestrians and vehicles, the cars must of necessity travel at slow speed, and do not, therefore, require the full pressure, while in the suburbs speed is a matter of importance for business men coming into and leaving the city; and in Cincinnati it was particularly necessary to keep the pressure up, owing to the hilly nature of the suburbs. The power houses, I found, were built in the suburbs in situations most suitable to deliver highest pressure where most required. Short circuits being of very frequent occurrence, magnetic cut-outs were placed on the feeder and dynamo mains at the switchboard, and in some cases on the machines as well. With built-up fly-wheels of the ordinary type, it is well known that the maximum linear speed of the rim must not exceed a certain limit of, say, 6,000ft. per minute. Centrifugal force acting radially outwards tends to bend those portions of the rim lying between spokes, putting the outside of the rim in tension and the inside in compression. What the stresses due to bending actually are need not be gone into here, but it is evident that the safe factor between bending moment and circumferential tension of the rim rapidly diminishes as the limiting velocity is exceeded, and from this cause wheels occasionally fly to pieces without any previous warning. The large amount of energy stored in these 25ft. and 30ft. fly-wheels answered the purpose of keeping the volts up under sudden increases of load, but were somewhat a cause of anxiety when short-circuits came on. Either the magnetic cut-out did not act quickly enough and the inertia of the driving power kept the dynamo up to speed and forced it to a burn-out, or the engine raced to a dangerous extent on the quick withdrawal of full load Some instances of these came under my own observation. At the Hunt-street power house in Cincinnatti, where there are intermediate lines of countershafting between engines and dynamos, I noticed some repairs being effected, and was informed that seven pulleys on one line of countershafting had flown to pieces on the occasion of one main engine racing, and that the broken pulleys had smashed an equivalent number of dynamos which they were driving. I was then shown an ingenious arrangement that had since been added to the Corliss cut-off gear, in preparation for the next occasion of racing, by which steam could be instantly cut off the engines by pulling a cord which came over a pulley on the ceiling. These cords were dropped down at various points in the station, so that a man, say at the switchboard, could instantly stop any engine. Pulling the cord released a weighted lever, which moved a cam into such a position under the trip gear that steam was completely shut off

* This paper, which will be discussed before the Institution of Electrical Engineers, is taken from the *Journal* of the Institution.

Digitized by Google

during the whole of the stroke. At the time of my visit to the Atlantic Avenue Street Railroad power house in Brooklyn, broken parts of one of the large fly-wheels, together with a generator, were just then being taken out through an opening in the station wall, which, with part of the roof, had been demolished by the flying pieces of a racing engine. The facts were fully reported in the American Press at the time, and the engineer in charge was highly spoken of for the manner in which he endeavoured to avert the catastrophe. On account of the uncertainty of cut-outs it was generally considered that the generators should be under-engined, thus allowing a margin for overload. I found, on the other hand, that some of the more recently planned power stations were equipped with direct-coupled plant; and the tendency of advanced practice in America, if one may take the plant at the World's Fair as an indication, was certainly towards direct driving. The General Electric Company, who completely equipped the very successful elevated electric railroad of three miles in extent through the Exposition grounds, used for the most part generators coupled both to horizontal and vertical engines; while the Westinghouse Electric Company supplied power to the moving sidewalk from a large dynamo taking the place of a fly-wheel between the high and low-pressure sides of a cross-compound horizontal engine. This company also exhibited a 160 h.p. generator direct-coupled to a Westinghouse high-speed engine, such as is regularly used in their power stations. I also saw well-arranged direct-driven sets in the power houses at Milwaukee and Cleveland. At the former place there was a very large Edison plant, with boilers on an upper floor and engines below. The engines were of 600 h.p., vertical, triple-expansion, condensing, each driving two 200-kilowatt generators. At Cleveland the power house of the Cleveland City Railway Company contained four vertical triple-expansion condensing engines, by the Globe Manufacturing Company of Cleveland, of 560 h.p., three driving two 190-kilowatt four-pole generators each, and one driving one six-pole generator; the maximum output of the station being 2,800 amperes at 500 volts. These engines were fitted with Joy's valve gear, controlled by a small centrifugal governor through the medium of a hydraulic valve. Dynamos were very carefully insulated from earth, in some cases by half an inch of sulphur under the rails, and in all cases by wood under the bed-plate, and where direct-coupled the coupling was insulated. This precaution is necessary where overhead wires are used, on account of lightning, to prevent a side flash between coils and framework. When a flash does pass by the machine, the damage is caused by the current of the machine following up the flash. The "magnetic blow-out" and "air-blast" arresters are being supplanted by Wurt's water-tank arrester, in which there is no spark gap. The well-known action of lightning in choosing to flash from coils to frame, instead of through magnet and armature coils to earth, on account of self-induction in the latter, is utilised in preventing its reaching the machine at all. Coils are placed in the line circuit—a sufficient number being in multiple to carry the current—and from these at intervals connections are tapped to carbon rods dipping into water in a tank. Lightning is checked by the induction of the coils, and discharges by the rods and water to earth. By the use of running water the normal loss from generators is reduced to a very small amount; and by using a small branch from the city water mains, with overflow pipe for this purpose, the additional advantage is gained of a good earth. I found that a good deal of power was tapped off the 500-volt tramway circuits for supplying private motors. On the Cleveland Electric Railway Company's system there was 350 h.p. taken off for this purpose, the motors varying in size from $\frac{1}{2}$ h.p. to 25 h.p. The tariff charged was 20s. per month per h.p. for 3 h.p. and over, or at the rate of 4d. per horse-power hour; the horse-power being averaged by a portable meter kept on the circuit for a given time.

Improvements have been made in the design of street car motors, their attachment to car trucks, and in decreasing their weight for a given output. Through the courtesy of the General Electric Company I am able to give a few particulars of their latest type of 25 h.p. motor, known as the "G.E. 800 Motor." This name is stated to be given to it on account of the drawbar pull exerted by the motor being 800lb. on ordinary street tracks, with 33in. car wheels, the usual single reduction gear, and rated current. The dead weight has been reduced to 1,450lb., or 730lb. below the former standard type of the same power—viz., the W.P. 50 (waterproof motor). Next to reducing the weight of the motor *per se* is the requirement of reducing dead weight on the axles and distributing it over the car. By the usual end suspension about half the weight is carried by the axle, and half by a cross-bar resting on springs; but by a new arrangement with side-bar suspension (Fig. 19), the whole of the weight is taken off the axle. The side-bar, B, takes the weight of the motor at the trunnion, E, and is itself supported by link bars bolted to the frame at the back (A), and by six springs in front at F, four of which take the weight, and two resist upward pressure. The wear and tear of the track is by these devices considerably reduced, and the running of the cars improved. The motor is enclosed in a cast-iron frame, in two parts hinged together, the same forming the field. There are two field coils, one in the upper and the other in the lower portion of the field; and, as these are wound to give similar poles, two additional consequent poles are formed between them, making a four-pole machine. The armature is cross-connected, so that only one pair of brushes is used; and these, with the upper field coil and armature leads, are fixed inside the upper half-frame and swing back with it. The iron of the field is of course to earth, and therefore special care is necessary to insulate the field coils; but the chance of a fault is minimised by coupling the coils to the earth return, in which case they can only vary by a few volts from the potential of the frame itself. The axle gear, which runs in an oil chamber, is arranged for a speed reduction of 4·78. The latest type of Westinghouse motor for street cars is built in a cast-iron horizontal frame, on which are hinged the upper and lower field magnets, so that the armature can be got at from above or below. There are four field poles, with as many coils. The armatures are drum-wound, each coil being wound on a former of the size of a quarter the circumference of the core, then taped, and slipped into its place between the teeth of the core. The wires composing the coil are laid so as to form a flat strip, which goes in edgewise between the teeth and lies flat at the ends of the drum, so economising space. The whole is then covered with waterproof material.

There are various types of "controllers," or combination switches, for putting the two motors on a car in series and parallel. The switch handle has from five to ten notches, giving different grades of speed. The first, or starting, position puts the motors in series through resistances; the succeeding steps reduce the resistances, shunt one motor out of circuit, and finally put both in parallel. There is also a side lever operating a cylinder of contacts for reversing the motors. I tried the experiment on one of these controllers of making the motors act as an electrical brake. Getting them first up to full speed, the controller was put back to starting position, current switched off, motors reversed, and then put in parallel again. The slight difference in excitation between the motors then caused one to act as a generator and drive the other, making a very powerful and quick-acting brake. A single switch might be employed which would effect these changes, and so prove an important aid to the mechanical brake in an emergency.

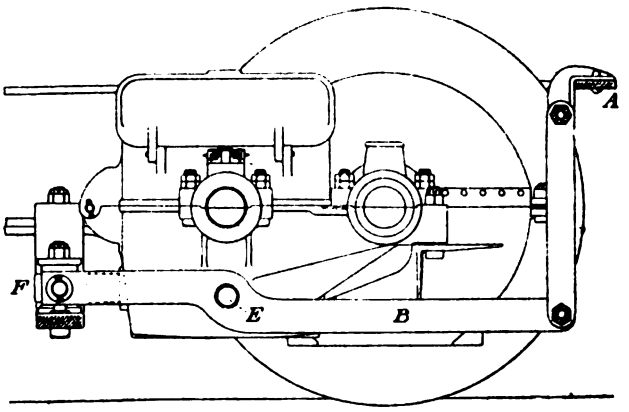

FIG. 19.—Side Suspension of Motor.

In Philadelphia I found very few streets with overhead wires, and learnt that an active policy had been pursued by the City Electrical Bureau towards the placing of all electric wires underground. One overhead trolley line was in operation, but the feeder cables were all in underground cement-lined conduits. Mr. D. R. Walker, chief of the Electrical Bureau, informed me that he, in company with the director of the Department of Public Safety, had examined into the systems of electric traction in other cities, with the view of employing the most suitable for the city of Philadelphia. He referred me to his report, which summed up as follows: "The overhead system of electric propulsion of street cars is, in my opinion, better fitted for small towns or villages, or to connect the same, or for the suburbs of a city such as our own; but when it comes to introduce electricity as a motive power in the heart of a large city, the circuits conveying the power for the same can, and should, be placed beneath the surface of the street. It has been effectually proven a success in Chicago, and is now being introduced to a large extent in Washington, D.C.; and any new privileges asked for in this direction should be granted only on condition that all the wires used for such a purpose should be placed underground. The only difference between the overhead and underground systems is in the matter of cost, which is but a secondary question when the safety and comfort of our people, and maintaining the beauties of our thoroughfares, are concerned. Again, a more reliable service can be maintained underground than overhead, as it would be free from interruptions caused by fire, falling of wires, or the action of the elements. The franchises so granted are immensely

Digitized by Google

valuable, and while they are being issued the interests of the city should be taken into consideration, and provision made underground for its electrical systems and for the lighting of its highways."

I may mention incidentally that the city authorities use, or own and rent to private companies, about 25 miles out of the 150 miles of underground conduit laid. I refer here to conduits constructed for the reception of electric cables and feeders, not for tram-car propulsion. The wires owned by the city are for telegraph and telephonic communication from the City Hall to fire and police stations and street call boxes, of which there is a most complete system, and for the electric lighting of the streets. The city contracts with lighting companies to supply lamps and current only, posts and cables being erected and laid by the city. I was very much impressed with this imposing and beautiful city, and with the system of control exercised in the interest of the citizens over all electrical undertakings by the electrical bureau.

Of the 12,000 miles of tramway in the United States and Canada, about 7,200 miles are operated by electricity, and 3,500 miles by horses. In conclusion, I need only remark how well adapted electric traction is to the wants of the people. Following the ordinary highways, where business is done and people congregate and travel to and fro, tramways afford at once a means of locomotion that is readiest to hand with least trouble to the traveller. For short distances, people will not go out of their way to get on the railway, or climb steep staircases to elevated roads, provided that the street tramcars travel at a reasonable speed, with minimum delay. For the latter desideratum a modification of the American practice in cities of not stopping between "blocks" might be adopted, while for a reasonable speed we must look to other means of propulsion than horses. The cable system is very suitable in certain localities, such, for instance, as on straight and hilly roads, but the wear and tear of cable is enormous on curves. Steam is unsightly and obnoxious. Electricity affords at once rapid and noiseless travel, quick control, with small wear and tear, and the current can simultaneously be utilised for heating and lighting the cars. As a means of travel, I have not experienced in the States anything so pleasant as their well lighted and fast moving electric street cars; and I cherish the hope that ere long this public boon may be extensively put into action along the streets and lanes of our own country.

ELECTRIC POWER, HEATING, AND LIGHTING.*

BY G. BINSWANGER, M.I.E.E.

I feel confident that the invention of the electric motor will revolutionise the planning and building of our factories. At present our mills and factories for the most part are driven by steam power, and it is essential to bring the machines as near the source of power as possible, in order to avoid the cost and waste inherent in transmission by shafting and belting. No such consideration need affect the designing of our factories in the future. The power of the electric current can be transmitted easily, cheaply, and practically without loss through two wires; the motors can be placed directly near or upon the machines to be driven. Not only will the factory buildings themselves be constructed on different lines owing to this fact, but I look forward to an increase of home industry in which the several members of a family may be employed. From a social and economical point of view, this will prove a great advantage to many an industry and to many a community. It will, of course, receive due consideration in planning the construction of our workmen's dwellings. I look forward to the employment of electric motors in large public buildings, hotels, and in private houses.

I believe ventilation is an important question for architects, and one which has not yet found a definite solution. The usefulness of the electromotor in driving fans for ventilation has been again and again demonstrated and recognised. There can be no doubt that it will be employed largely for this purpose in the future, and will therefore have a considerable influence on the construction of buildings that require proper ventilation. At present lifts are only used in large buildings because the power required is costly, or requires room, or cannot be obtained conveniently. No doubt, with such a source of power as the electric current within the reach of private houses, we may look forward to seeing lifts, cranes, and other methods of mechanical conveyance introduced into smaller houses. I suppose the want of such mechanical conveyance is now influencing the construction of many a house. Why should the kitchen be near the dining-room if we can get our dishes sent into the room by merely pushing a button? Electric cranes have done good work in docks, and are much preferred to steam cranes. I think they will be largely employed in many of the operations necessary in the construction of buildings.

I will now refer to heating by electricity. Imagine a house built without flues, without chimneys, without hot-water pipes, and yet perfectly heated, perfectly ventilated, and with perfect cooking arrangements! Such a house could be built to-day if we call electricity to our aid. Many such houses, I doubt not, will be built within a not too distant period. Imagine the question of smoke abatement solved in this way! To heat the atmosphere in our rooms we make radiators or stoves; we can heat either by radiation or convection. Here is such a radiator, the heat produced in the wire resistance embedded in the cement is transmitted to an iron surface having many projections and blackened. It requires a current of 10 amperes at 100 volts to warm a room of about 3,000 cubic feet. This method of heating the atmosphere by electricity is still too young to predict the success of its ultimate employment, in preference to heating by coal or gas.

I do not purpose dilating upon the advantages of the electric light, its beauty, safety from fire, non-consumption of oxygen, its decorative uses, etc. All these have been dwelt upon so often. But may I seize the opportunity I now have of talking to architects to say a few words upon a subject in connection with electric lighting, a subject which, to my knowledge, has so far received but little ventilation before architects, to whom it must mean a good deal. This subject is: the wiring for the electric light. The method adopted in this and many other countries is to run two wires in wood casing, having two grooves in it. This method is a compromise between the electrical engineer and the fire insurance inspector; the third party who ought to have a voice in the matter has never been consulted—I mean the architect. I have heard many architects complain that this method is one which does not commend itself to them; it is difficult, and sometimes impossible to provide for it in new houses, and often disfigures the walls of existing buildings, to be installed with electric wires. By some it is looked upon as a necessary evil. I may affirm that this need not be so. We are not married to this system. I feel confident that a departure from present arrangements could be effected which would be appreciated both by the builder and the architect. I feel sure that the co-operation of the architect and electrical engineer will eventually produce such a modification as is felt to be desirable, and even necessary, by the electrical profession itself.

This brings me to say a few words about the education in matters electrical of an architect. Doubtless many a one is giving the subject his earnest consideration, but I think all architects should acquaint themselves with the elements of applied electricity. He ought to be familiar with the properties of wires, their carrying capacities, their resistances, and of materials used for insulating those wires necessary to fit them for use in electrical installations. A knowledge of these and similar subjects would be of considerable service to him in preparing his plans for our modern buildings, which will be all the better for being supplied with all the comforts and luxuries capable of being bestowed upon us by making electricity our servant.

I have so far refrained from referring to what would be the cost of employing the electric current for the purposes I have been speaking of. Doubtless, you will say, here lies the crux of the whole question. There can be no doubt that the operations can be performed, but they would be of little practical value, if their cost should be beyond your client's means. My reply to this is, that the cost is not excessive, or beyond the means of the moderately rich, even at the price at which the current is being generally sold, but there are indications and grounds sufficient at hand that may lead us to expect that one day electricity will also supply energy for light, power, and heat to the poor. The present ruling price is capable of being reduced, and the very fact of its being used for motive power and heating will necessarily bring down such price.

At present the average charge for current is 6d. per unit for lighting and 3d. per unit for other uses during the day. Mr. Crompton, in a paper on the cost of electricity, gives the actual works cost of current—that is, for coal and wages—at ½d. per unit. The rest of the cost, such as maintenance, interest on capital, and management, is in a measure governed by the load-factor, or the proportion to daily load compared with the capacity of the plant, and if this is large and well distributed, as it will be if heating, cooking, and motive power come to be used, the percentage of such extra cost to be charged in each unit will be small, and we may look forward to seeing electricity sold in our houses at or near 2d. per unit—a price at which electricity will be able to compete with coal or gas for light, as well as for power and heat, and be in many instances cheaper.

We may with confidence look forward to being able to obtain, at a not too distant period, cheap electric energy, concurrently with perfect and economical apparatus, for employing it for lighting, power, and heating. In view of this, architects will do well to contribute to the early and general adoption of electricity for such purposes, and thorough co-operation of architects and electrical engineers will, I feel confident, be of great value, and conducive to the furtherance of the objects which this Congress of Public Health has at heart.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

REPAIR OF LAND-LAID CABLES.

We have always had a great appreciation of the work of submarine cable engineers and electricians. When properly done, their work can only be characterised as thorough, and those engaged in the newer developments of electricity have never sufficiently examined the accumulated knowledge of old cable workers. We are led somewhat to emphasise these conclusions from reading two able reports by Mr. Chas. Bright to the Silvertown Company—one on the repair of a land line, the other on the repair of a beach section of cable. The former has more interest to us than the latter, for electrical engineering is world-wide, and the burying of cables, electric light or otherwise, is as extensive. Telegraphists especially will be glad to know that the Silvertown Company has printed these reports, copies of which are to be found in various public libraries. But electric light cables, telegraph cables, and telephone cables have much in common when laid underground. They develop faults from various causes, and have to be repaired. These repairs are costly, and if the faults arise from neglect in manufacture, carelessness in laying, or being put into the wrong place, any information on these points is valuable. It is singular, for example, how persistent are certain mistakes in laying cables. It is known many a cable fault has been caused by the fraying of the cable hanging over a couple of rocky points, too little slack having been paid out to allow it to rest on the ocean bed. One would not expect faults of an exactly similar character to be found in trench-laid cables, but something very much of the same kind goes on, as was found in this repairing expedition. Not a fraying through motion, but a too little regard for the conformation of the ground; hence too great a strain at the bend of the cable through a valley trench. Then deterioration takes place through alternations of wet and dry, aided by a high temperature—three causes which may be found acting almost everywhere. In the particular case described the wind was the moving agent acting on a sandy soil. This, heaped up in one place and denuded in another, buried the cable deep under the surface in one place while leaving it near or quite at the surface in another, as well as putting an extra strain upon the cable from the accumulating weight of material at the ends of the bend. This report is exceedingly interesting reading, also, in that it discusses minutely every detail of the repairing operations, pointing out how wrong steps were taken in the original laying, and why these ultimately led to the development of faults. As yet electric light cables are in their infancy. They are in big towns laid in a different manner to the laying of this telegraph cable in Africa, but we are quite sure that electric light cables will from time to time develop faults, and have to be repaired. In fact, many of them have only during recent years been laid without that careful factory testing to which telegraph cables are continuously subjected, though it speaks volumes for the more prominent makers in saying that early in the

Digitized by Google

industry they saw the necessity for such testing and subjected their manufacture to it, so that of late years the life history of a piece of electric light cable can be as easily ascertained as the life history of a piece of submarine cable. To the telegraph engineer these reports are of the greatest importance. They are the first, so far as we know, to exhaustively discuss the repair of land-line links in tropical climates. There seems to be no point overlooked. The type of cable, its insulation in particular places, the best depth at which it should be laid, jointing, etc., each and all are examined, and the reasons given for the adoption of the course pursued. We must congratulate Mr. Bright upon the admirable way in which he has presented these reports, and the Silvertown Company for having printed them and by placing them in various public libraries put them at the disposal of anyone who desires to consult them.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE SECOND ATLANTIC CABLE.

SIR,—Would you kindly tell me who laid the second Atlantic cable?

I used to be under the impression that Sir Charles Bright laid the first Atlantic cable, and that Sir Samuel Canning (as engineer-in-chief) was responsible for the laying of the second Atlantic. Lately, however, I have heard Sir James Anderson referred to so many times as being the person to whom we are indebted for it (as well as Cyrus Field for the first Atlantic) that I really don't know *what* to think. It is quite clear that some one man was in *charge* of the cable work, and I should much like to know who this really was.

The question has cropped up again recently in connection with the Eastern Telegraph Company's banquet at the Imperial Institute, when, according to the *Electrician* (which appears to have been the only electrical paper that was in a position to report the speeches)—the journal which, I understand, is the official mouthpiece of the "cable ring"—Sir John Pender seems to have said: "It was proved by our late colleague, Sir James Anderson, to be possible to pick up and repair a cable in 2,000 fathoms of water." On reading this in the *Times*, I thought it must be a mistake on the part of the reporter, so waited for the issue of the *Electrician* for verification—and got it. This would lead one to suppose that Sir James Anderson has been, at some time or another, placed in charge of a cable expedition—repairs, if not laying—and I should much like to know *which* one, if you can inform me.

Captain Anderson I have heard of as the gallant captain of the "Great Eastern" steamship—a very big ship, too, with several funnels, two paddle-boxes, and two screw propellers to be answerable for—but I did not know of Sir J. Anderson (afterwards the able manager of the Eastern Company) in the light of a cable engineer, and I should be glad to be further "posted up" in this subject if I am all afield.

Maybe it is hard for some people to realise that they are not, amongst themselves, responsible for *all* the cables laid—old as well as young.—Yours, etc.,

ENQUIRER.

Presentation.—The presentation of a handsome timepiece has been made to Mr. Burbey by the employés of Messrs. Burbey, Williamson, and Joseph on the occasion of his leaving the firm. Mr. Burbey being very popular with the employés, much enthusiasm prevailed, and the expression of good wishes for his future success were unanimous.

PRACTICAL NOTES ON DYNAMO CALCULATION.*
VIII.

BY ALFRED E. WIENER.

Experiments on the variation of the hysteretic loss per cycle as function of the temperature have been made by Dr. W. Kunz,† for the temperatures up to 800deg. C. They show that with rising temperature the hysteresis loss decreases according to a law expressed by the formula

$$H = a + b\,t,$$

where H = hysteresis loss per cycle, in ergs;
t = temperature, in centigrade degrees;
a and b = constants for the material, depending upon the temperature and on the maximal induction.

The decrease of the hysteretic loss, consequently, consists of two parts: one part, $b\,t$, which is proportional to the increase of the temperature, and another part, a, which becomes permanent, and seems to be due to a permanent change of the molecular structure, produced by heating. This latter part, in soft iron, is also proportional to the temperature, thus making the hysteretic loss of soft iron a linear function of the temperature, but is irregular in steel.

The curves in the latter case show a slightly ascending line to about 300deg. C., then change into a rapidly descending straight portion to about 600deg. C., when a second "knee" occurs, and the descension becomes more gradual.

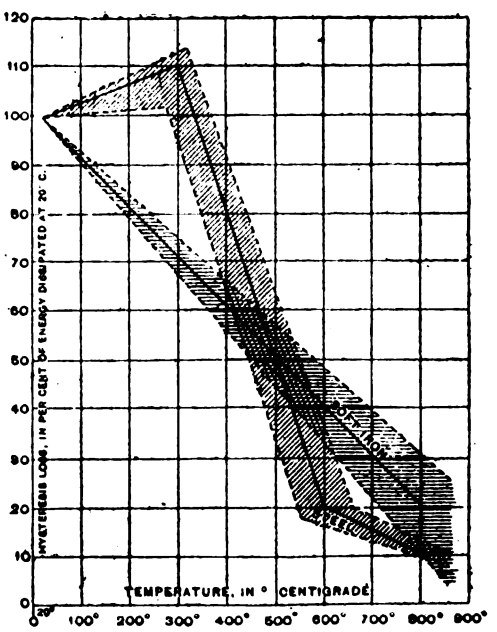

FIG. 15.

The writer has refigured all of Kunz's test results, basing the same upon the hysteresis loss at 20deg. C. as unity in every set of observations. In Fig. 15 dotted lines have then been drawn, enclosing all the values thus obtained for soft iron and for steel respectively, and two full lines, one for each quality of iron, are placed centrally in the planes bounded by the two sets of dotted lines, thus indicating the average values of the hysteretic losses, in per cent. of the energy loss at 20deg. C. Arranging the same in form of a table, the following law is obtained:

TABLE XXVI.—Variation of Hysteresis Loss with Temperature.

Temperature in centigrade degrees.	Energy dissipated by hysteresis in per cent. of hysteresis loss at 20deg. C.	
	Soft iron.	Steel.
20	100	100
100	90	103
200	80	106
300	70	110
400	60	80
500	50	50
600	40	20
700	30	15
800	20	10
20	70	40

* From the *Electrical World* (New York).

† Dr. W. Kunz, "Elektrotechn. Zeitschr.," vol. xv., page 194 (April 5, 1894); the *Electrical World*, xxiii., page 647 (May 12, 1894).

Digitized by Google

The last row of this table, which give the hysteresis loss at 20deg. C., at the end of the test, shows that the energy required to overcome the hysteretic resistance is reduced to about 70 per cent. in case of soft iron, and to about 40 per cent. in case of steel, after having been subjected to magnetic cycles at high temperatures. Kunz further found that the hysteretic energy loss can thus be considerably reduced by repeatedly applying high temperatures while iron is under cyclic influence.

For soft iron a set of straight lines was obtained in this way, each following of which had a lower starting point, and descended less rapidly than the foregoing one, until, finally, after the fourth repetition of the heating process a stationary condition was reached.

For steel, already the second set of tests with the same sample did not show the characteristic form of the, at first ascending, then rapidly, and finally slowly, descending steel curve, but furnished a rapidly-descending straight line. For every further repetition the corresponding line becomes less inclined, and for the fifth test is parallel to the axis of abscissæ. Steel, therefore, after heating it but once as high as 800 deg. C., loses its characteristic properties, and with every further repetition becomes a softer, less carbonaceous iron.

c. Energy Dissipated by Eddy Currents.—From his experiments, Steinmetz also derived that the energy consumed in setting up induced currents in a body of iron increases with the square of the magnetic density, with the square of the frequency, and in direct proportion with the mass of the iron:

$$H_2 = \epsilon_1 \times B^2 \times N_1 \times M_1 ;$$

H_2 = energy dissipated by eddy currents in ergs;
B = density of lines of force per cm.^{2} of iron;
N_1 = frequency, in cycles per second, $= \frac{N}{60} \times P$;
M_1 = mass of iron, in cm.^{3};
ϵ_1 = constant, depending upon the thickness and the specific electric conductivity of the material:

$$\epsilon_1 = \frac{\pi^2}{6} \times \delta_1^2 \times \gamma_1 \times 10^{-9} = 1{\cdot}645 \times \delta_1^2 \times \gamma_1 \times 10^{-9}.$$

δ_1 = thickness in cm.;
γ_1 = specific conductivity in mhos.;
for iron, $\gamma_1 = 100{,}000$ mhos.;
for copper, $\gamma_1 = 700{,}000$ mhos.

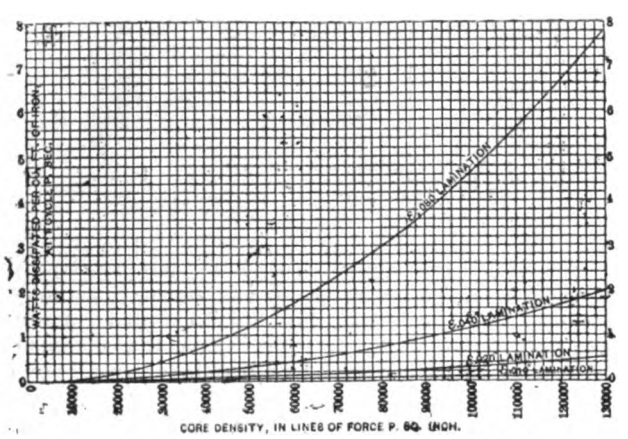

FIG. 16.

Inserting the value of ϵ_1, with reference to iron, into the above formula, and transforming into practical units, the eddy current loss in an armature, in watts, is obtained:

$$w_e = 10^{-7} \times 1{\cdot}645 \times (2{\cdot}54\,\delta)^2 \times 10^{-4} \times \left(\frac{\mathfrak{B}_a}{6{\cdot}45}\right)^2 \times N_1^2 \times$$

$$28{,}317 \times M\pi = 7{\cdot}22 \times 10^{-8} \times \delta^2 \times \mathfrak{B}^2{}_a \times N_1^2 \times M \quad . \quad (40)$$

δ = thickness of lamination, in inches;
$\mathfrak{B}_a$ = core density, in lines of force, per square inch;
N_1 = frequency, in cycles per second;
M = mass of iron, in cubic feet.

Uniting again $7{\cdot}22 \times 10^{-8} \times \delta^2 \times \mathfrak{B}^2{}_a$ into one factor, in this case the eddy current factor, ϵ, we have the simplified formula:

$$w_e = \epsilon_1 \times N_1^2 \times M \quad . \quad . \quad . \quad . \quad (41)$$

The values of ϵ for core densities from 10,000 to 125,000 lines per square inch, and for laminations of thickness, δ = ·010″, ·020″, ·040″, and ·080″, are given in Table XXVII.

TABLE XXVII.—Eddy Current Factors for Different Core Densities and for Various Laminations.

(d) Total Energy Loss in Armature.—The total energy transformed into heat in the armature is the sum of the

Digitized by Google

energies consumed by the winding, by hysteresis, and by eddy currents:

$$W_a = w_a + w_h + w_e \quad . \quad . \quad . \quad (42)$$

W_a = total watts absorbed in armature;
w_a = watts consumed by armature winding, formula (35);
w_h = watts consumed by hysteresis, formula (39);
w_e = watts consumed by eddy currents, formula (41).

For comparison, in the preceding Table XXVIII., the energy losses due to hysteresis and eddy currents, expressed in various units of the metric as well as the English system, are compiled.

17. *Radiating Surface of Armature.*—The radiating surface, or cooling surface, of an armature is that portion of its superficial area which is in direct contact with the surrounding air, and which consequently gives off the heat generated in the winding and in the iron core. It is evident that the shape and the construction of the armature and the arrangement of the field determine the size of this radiating portion of the armature surface. In drum armatures, for instance, only the external surface is liberating heat, while in ring armatures, according to design, either the external surface only, or any two or three sides of the cross-section, or even the entire superficial area, may act as cooling surface.

(*a*) *Radiating Surface of Drum Armatures.*—In drum armatures the dead portion of the winding forms two "heads" at the ends of the cylindrical body, and the external area, extending over the cylindrical part, as well as over these two conical heads, is the radiating surface of the armature. In order to calculate the cooling area of a drum armature, it is therefore necessary to first determine the size of the armature heads.

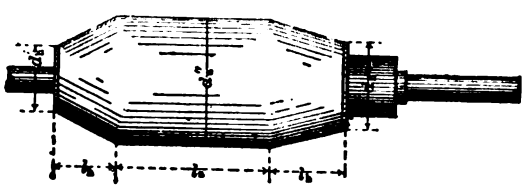

FIG. 17.

The length of the heads, l^h (Fig. 17), depends upon the diameter of the armature, the size of the shaft and the height of the winding space, and can be found from the empirical formula:

$$l_h = k_7 \times d_a'' + 2 \times h_a \quad . \quad . \quad . \quad . \quad (43)$$

where l_h = length of armature heads, in inches;
k_7 = constant, depending upon the size of the armature (see Table XXIX.);
d_a'' = external diameter of armature, in inches;
h_a = height of winding space, in inches.

The coefficient, k_7, in this formula varies with the slope of the head, and this, in turn, depends upon the ratio between the diameter of the armature and the thickness of the shaft. For in large machines the shaft bears a smaller proportion to the armature diameter than in small ones, and therefore in large armatures there is comparatively much more room between the shaft circumference and the body periphery than in small armatures, and since the diameter of the head must never exceed that of the armature itself, it is evident that the slope of the head is smaller, and consequently its relative length is larger in the smaller armatures. The following Table XXIX. gives the values of this coefficient for the various sizes of drum armatures:

TABLE XXIX.—Length of Heads in Drum Armatures.

External diameter of armature. d_a''.	Value of k_7.	Average length of heads. l_h. Inches.
Up to 6"	·60 to ·50	$l_h = ·55 \times d_a'' + 2\,h_a$
„ 12"	·55 to ·45	$= ·50 \times d_a'' + 2\,h_a$
„ 18"	·50 to ·40	$= ·45 \times d_a'' + 2\,h_a$
„ 24"	·45 to ·35	$= ·40 \times d_a'' + 2\,h_a$
„ 30"	·40 to ·30	$= ·35 \times d_a'' + 2\,h_a$

As to the diameters at the ends of the heads, that of the front head, d_h, at commutator end of armature, is generally made from $0·75\,d_a''$ to d_a'', while the diameter of the end washer of the back head, d_h, ranges in size from $0·5\,d_a''$ to $0·75\,d_a''$. Taking $d_h = 0·9\,d_a''$ as the average diameter of the front head, and $d_h = 0·6\,d_a''$ as that of the back head, Figs. 18 and 19, we obtain the following formula for the radiating surface of a drum armature:

$$O_a = d_a'' \times \pi \times \left(l_a + 1\tfrac{3}{4} \times \sqrt{l_h^2 + \left(\frac{d_a''}{8}\right)^2}\right),$$

or, approximately

$$O_a = d_a'' \times \pi \times (l_a + 1·8 \times l_h) \quad . \quad . \quad (44)$$

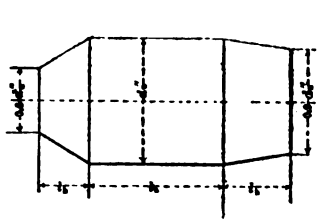

FIG. 18.

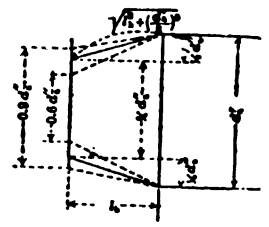

FIG. 19.

O_a = radiating surface of armature, in square inches;
d_a'' = external diameter of armature, in inches;
π = $d_a + 2 \times h_a$;
l_a = length of armature body, in inches, formula (12);
l_h = length of armature head, in inches, from formula (43).

(To be continued.)

ELECTRIC WELDING.*

BY BENJAMIN ALFRED DOBSON, MEMBER OF COUNCIL

EXPERIENCE IN ELECTRIC WELDING.

Practical everyday working for nearly three years of the process of welding by electric force enables the author to give certain indications and appreciations of the method considered as a practical workshop operation. During this period his firm has had two machines in operation, worked from the same generating dynamo, and employed on different classes of work: one is specially arranged for piecing bar iron and steel; and the other and smaller machine for special classes of work of a more delicate description, such as brazing and the piecing of clean-finished work, where the fire heat would have destroyed the quality of the work on the adjacent material. The statement made with regard to the requisite mechanical power placed great difficulties in the way at first, as it was found that this power had been much understated. Having something like 35 i.h.p. to spare on a certain engine, and understanding that 30 h.p. would be the utmost wanted in order to piece a 2in. round bar, the author determined to drive the dynamo from this engine, particularly as it was in close proximity to the smithy and stretching shed, where this piecing was previously effected by means of the ordinary smith's hearth. By this practical test it was found that not 30 h.p., but as much as 80 h.p. seemed to be required for the larger sizes; and until this was understood the engine was frequently stopped from want of steam, occasioning great loss and inconvenience. The company having control of the welding machine suggested that they should supply a semi-portable engine and boiler, and that this should be tried, with the option of purchase, after a certain length of time, if approved. This was agreed to, and a portable engine by Messrs. Marshall, of Gainsborough, capable of working up to 100 i.h.p. with 80lb. pressure, was supplied and placed at a distance of about 45 yards from the welding machine. This got over the difficulty of power, but was of course more expensive on the score of separate attendance and other cost. But even with this engine it was found that, when piecing the larger diameters—and as yet nothing over 2¼in. has been pieced—if the work was to be done within a reasonable time, the engine was seriously checked in speed. It was therefore with a view to be certain as to the basis of calculation for the necessary expenditure on driving power that the experiments which follow were conducted.

After some months' working with the portable engine, it was proved satisfactorily that the process was a practical one, and, so far as the results to the author's firm were concerned, a success. As considerable enlargements were about to be made to the establishment, a portion of a large dynamo-room for electric lighting purposes was set apart for the welding dynamo and exciter; the distance of the leads from the dynamo to the welding machine was approximately 100 yards. Having a quick-running vertical engine of the kind made by Messrs. Fleming and Ferguson, making 140 revolutions per minute,

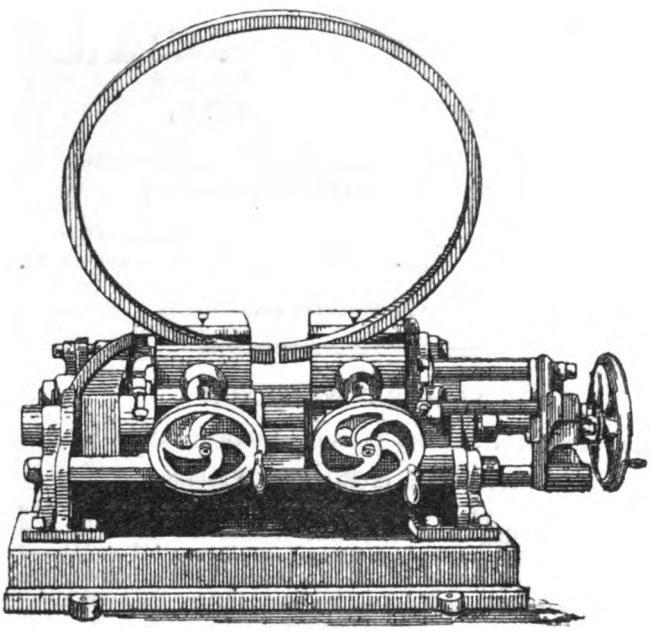
* Abstract of paper read before the Institution of Mechanical Engineers.

Digitized by Google

with an extra heavy flywheel and abundance of surplus power, the author has been able to work the larger diameters without affecting the steadiness of the arc lamps driven off the same engine; and as the load will vary 80 h.p. in the tenth of a second, this result speaks well for the arrangement of the engine and for its governing powers. The greatest variation in voltage of the lighting dynamos has been two volts.

Electric Welding Process.

The accompanying illustration shows the Elihu Thomson machine employed in welding a ring. The Thomson-Houston welding dynamo is an alternating-current machine. The field magnets project inwards from a cast-iron frame having six pole-pieces. Its speed is 1,000 revolutions per minute, and it gives at full load a current of 200 amperes at 300 volts, having a frequency of 100 complete alternations per second.



Welder with Hoop Ready to Weld.

The machine is excited from a continuous-current dynamo giving 40 amperes at a pressure of 110 volts. The large welder is capable of piecing iron or steel bars up to 2in. diameter. The primary coils consist of 41 turns of 0·452in. copper wire; these are coiled round an iron core formed of thin sheet-iron plates bolted together. The secondary circuit consists of a single massive copper tube 1¾in. diameter inside and 3¾in. outside, passing through the centre of the core, and connected at the two ends with massive castings 6¼in. broad by 3in. thick, which support the welding clamps; one clamp is kept stationary during the welding, and the other is movable. The pressure is obtained by a screw and hand wheel, forcing the movable clamp towards the fixed clamp.

Elihu Thomson Welding Process.

The heating effect of the passage of electric energy through a bar of any particular resistance is proportional, not to the amount of energy, but to the square of the current simply. In order, therefore, to obtain the greatest heating effect with a given amount of energy, it is advisable to use a very large current at a very small pressure. With this object an alternating current is employed in the Thomson process, and transformed down from something like 300 volts to one volt or even a fraction of a volt. The bar itself is held between two clamps of copper having a small resistance; and the portion of the bar to be heated for welding is that which lies between the two clamps, and which always has a much greater resistance than the clamps themselves or any other portion of the circuit. Even, therefore, if a solid bar be held between the two clamps, it becomes heated somewhere between the points at which it is held. If, however, as is the case for welding, the bar is not a solid one, but has a break in it at the point where it is to be welded together, then the greatest resistance in the circuit is at the surfaces of this break, where the contact is imperfect. Heat is developed here at once; and the surfaces being continuously pressed together by special apparatus, the metal as it softens is squeezed into closer contact, and eventually the two original separate pieces are thereby welded together.

Method of Working.

The method of working is somewhat on the following lines. The main carrying the current to supply the exciting coils of the alternator is conducted to the room in which the electric welder is placed. The main is attached to the terminal of a rheostat or resistance coil, and a return main is connected to the other terminal and is returned to the alternator, and from this another main is led back to the exciter. The rheostat now being in series with the exciting coils, governs the current of excitation, and thus controls the output of the alternator. A double-pole switch has one pole connected with the primary main leading to the primary coil of the electric welder, and the other pole connected with the exciting current main leading to the rheostat, so that this switch breaks the exciting circuit and also the primary circuit at the same time. When two pieces are ready to be welded, the double-pole switch is switched in, and the attendant adjusts the rheostat until the desired heat is obtained. The ordinary surfaces of bars, whether cut by shears or broken with the chisel and hammer, are found sufficiently uniform to permit of welding without further preparation. Should there be dirt or rust upon the surfaces, it is easily expelled when the metal is sufficiently soft to allow of the end pressure of the screw necessary to form union, and the dirt, scale, or oxide makes its way to the exterior.

In common practice at the author's works the following materials have been heated, and the undermentioned work has been performed. Welding of steel of every quality, iron of every description from crown to best roller iron and charcoal iron, steel and iron together, wrought iron and cast iron; different diameters of the same and different materials. Riveting in many varieties; work which previously had to be riveted cold, and which consequently left the strength of the parts uncertain, is now done easily, and certainly with the requisite heat. The piecing of countershafts and lathe spindles, where the question of exactness of length is of the utmost importance; screwing taps, rollers, and spindles broken in the neck bearings, and brazing of all descriptions have all been successfully treated. The alloys which have been tried have been done more for the purpose of experiment than for any useful end, and were not successful, owing to there not having been time to persevere sufficiently for ascertaining the precise temperatures and conditions under which the process could succeed.

Power Required for Electric Welding.

These tests have been confined to the welds required in everyday work, and have varied from ½in. steel and iron to 2in., as shown in Table I. The measurement of the alternating-current power supplied to the welding transformers is attended with some little difficulty, owing to the short space of time during which the current and E.M.F. are practically steady. As also every piece of iron varies in resistance, though cut from the same bar, the power registered is continually varying in the welding of bars of the same diameter. Another cause, accounting to some extent for the different powers obtained with the same size of shafting, is that the rheostat is not always worked from the same segment of the coils through the adding or deducting of the resistance, and consequently causes a greater or less excitation of the field of the alternator, thereby producing a greater or less E.M.F.

A Siemens electro-dynamometer was connected in series with the thick wire coil of a Siemens wattmeter, the latter being in series with the primary coil of the electric welder. Connected across the terminals of the welder was the thin wire coil of the wattmeter, in series with a non-inductive high resistance. A Siemens voltmeter for the measurement of alternating volts was also connected across the terminals of the welder. By this means the virtual volts and the virtual amperes were estimated with sufficient accuracy, and at the same moment a reading was taken from the wattmeter, giving the true watts absorbed in the transformer. At the time of taking the instrument readings indicator diagrams were taken from the engine, which afford a considerable check on the results obtained from the wattmeter. In order to estimate accurately the power taken for each weld, it is necessary to add the power required to excite the alternator and the power lost in transmission. For this purpose the resistance was measured of the mains supplying the current to the primary coil of the welder, and also the resistance of the mains carrying the exciting current; the former was 0·2 ohm, and the latter 2·6 ohms. The electrical horse-power given in Table I. is obtained from the true watts shown by the wattmeter, divided by 746, and the loss in the mains and in the exciting current is got by calculation; the loss in friction is the amount of power required to work engine, alternator, and exciter at no load.

Strength of Welds.

The following particulars are taken from Mr. Fish's draft paper, prepared for a former meeting of the institution, and, owing to the care with which the work seems to have been done, may be depended upon as correct. He says: "Twenty electric welds, bent hot, were bent through an average angle of 144deg. before cracking, Table II. In cold bending tests, however, the average with 20 pieces was only 66deg. before failure of the weld occurred. As a cause for this comparatively early failure, Sir Frederick Bramwell suggests the extreme localisation of heat in the electric welding process, and proposes annealing as a remedy. More recently a few welded bars, annealed either in the forge or by reheating a length of 5in. or

Digitized by Google

6in. in the welding machine immediately after the swaging and working of the weld was completed, have been tested by bending cold under the steam-hammer. The results were much more favourable than those obtained by Mr. Kirkaldy, the average angle of bend at which failure occurred being about 130deg. In testing welds of smaller sizes, the writer has experienced but little difficulty in bending the bars, while cold, round their own diameter; and he suggests that in the Farnley welds failure in the bending tests was hastened by error in the method employed in making and finishing the weld, as well as by any possible effect due to the localisation of heat.

"In testing Bessemer steel welds Prof. Kennedy obtained the following results:

Diameter of bar	1·00	0·75	0·50 inch.
Average tensile strength of welded bar in percentage of unwelded	92	97·5	100 per cent.

The decrease in efficiency of weld with increase in diameter would seem to be due to a proportionately smaller butting pressure during the welding. A high percentage of strength at the weld, 80 per cent. or upwards, and probably more than would be required in any practical test of the metal, can be obtained with most of the hardest steels. Most metals that are commercially pure, and certain alloys, weld with little loss of strength, except that which may be due to the annealing effect of the process; this loss may amount possibly to a total of 10 or 15 per cent. Tests made by Prof. Silvanus P. Thompson and others show that the electrical conductivity at the weld is practically the same as that of the unwelded material. This result is possibly an index of the soundness and homogeneity of the electric weld."

Conclusion.

The practical experiments made in the author's works show almost a better conclusion than the tests shown in published tables from the testing machine of the United States arsenal, for in bending cold here the weld has rarely given way. But in explanation of this it must be borne in mind that all the piecings of plain bars are here more or less swaged. It is well within the mark to state that there is not one out of 500 welds which turns out a failure or even defective. The question of cost, which of course is of importance to commercial engineers, has not been alluded to in detail. The author admits, however, that the payment of royalty, the cost of horse-power, and the depreciation which on electrical apparatus is heavy, together bring the cost considerably over the net cost of the ordinary smith's hearth work, while the actual payments in wages and so on are considerably less. The loss in weight of iron is about one-twentieth only. It may be taken that on straightforward welds the total cost will be between 10 and 15 per cent. more than the ordinary smith's work: whereas in delicate work and difficult operations, such as have been alluded to, the cost will probably be one-third of the smith's work. But the real advantage of the apparatus, at any rate as at present arranged, is not so much an economy as a method of securing an absolutely reliable result, and occasionally saving considerable expenditure by its special adaptability.

DESCRIPTION OF THE NEW ELECTRIC LIGHTING WORKS, MANCHESTER.*

BY DR. JOHN HOPKINSON, F.R.S., MEMBER OF COUNCIL.

The purpose of the present paper is merely to give a short description of the electric lighting works in Manchester, more particularly stating the minor points in which the arrangements differ from those most generally adopted. Although the differences from ordinary practice are small and comparatively unimportant, and involve nothing new in principle, a description of these works may be of interest on the occasion of the present meeting.

System of Distribution.

The system adopted is a direct continuous current, with five conductors supplying consumers at a pressure of 100 volts, the total pressure between the outer conductors being 400 volts. The conductors are partly bare copper in concrete culverts, and partly indiarubber insulated cables in cast-iron pipes. This arrangement of conductors is very similar to that which has been adopted in many other places, but is here carried out on a somewhat more extensive scale, the Portland-street culvert containing a total area of copper of 9¾ square inches. The sectional area of the three intermediate conductors is small—only ¼ square inch for each; whereas the total sectional area of the outer conductors in this case is no less than 4½ square inches. As might naturally be expected, such small intermediate conductors are in themselves inadequate to effect a perfect balance; the balance is therefore perfected by means of motor-generator machines fixed in outlying parts of the system. Each of these machines is wound with two circuits, so that the pair contains four circuits, each circuit being connected with two conductors of the five-wire system. The two

* Abstract of paper read before the Institution of Mechanical Engineers.

Digitized by Google

machines being connected mechanically with each other by a coupling, any excess of current demanded from one section will be supplied by the circuit connected thereto, and the power required to effect this supply will be derived from one or more of the other circuits. As a compensating device this arrangement is found to work perfectly; it does not claim any originality, as it has been in use for some time in many places. Electricity can be supplied to consumers at four different pressures, according to their requirements.

Insulation.

The system of bare conductors has the disadvantage that the general insulation is poor; but this really causes no trouble, as it is a general small leak over the whole system, and does not tend to get worse. There is one curious fact in connection with this defective insulation; the insulation of the positive conductor is always good, while that of the negative is always bad. The fact has been generally known for some time, but the author did not realise its importance till he experienced it. Electrolysis will deposit upon the negative conductor hydrogen from the moisture on the insulators; hence this exceptionally defective insulation is not calculated to injure the conductor. The explanation, so far as the author is aware, was not known. The difference in insulation between the positive and negative conductors arises from electric osmosis, which may be explained as follows. Suppose two vessels containing water to communicate by a cotton wick, and two electrodes differing much in potential to dip into the two vessels, then it is found that water passes over continuously from the vessel into which the positive electrode dips to that into which the negative electrode dips. This fact has long been known to physicists as a laboratory experiment. Next, suppose two electrodes to be carried on porcelain insulators which dip into water, and the water to be maintained at earth potential, and the two electrodes to be one positive and the other negative, then if the current leaking from each electrode into the water be measured, it is found that the leak from the negative is many fold the leak from the positive; this experiment the author has himself tried. The action of bare conductors is the same upon a large scale. The main source for moisture is from the walls and floor of the culvert; this moisture will constantly creep over the porcelain insulators towards the negative conductor, but will creep away from the positive conductor, drying the neighbourhood of the latter and improving its insulation. With the five-wire system the troubles have been few, and all easily met; with the bare conductors there have been no troubles at all.

Switchboards.

The switchboards are very simple and compact. The feeders are connected to vertical bars, each feeder to one or other of a pair of bars through a single two-way switch at the bottom of the pair of bars. The pole of each dynamo machine is connected through a switch to a horizontal bar of its own; and the horizontal and vertical bars are connected to each other by removable screw plugs. Suppose feeder No. 1 is connected to machine A through the left-hand vertical bar, and that it is desired to change this feeder to machine B. For this purpose a screw plug is put in for connecting the horizontal bar of machine B to the right-hand bar of the feeder, and the switch is thrown over, so as to connect the feeder to the right-hand bar, and to disconnect it from the left-hand bar. The change is thus effected in a fraction of a second. The double switches at the end of the horizontal bars have to do with exchanging from one machine to another. A resistance of about three ohms is permanently interposed between the two sections of each switch, and one section is permanently connected to the conductor from the machine. On each bar is an ampere indicator, competent to show when the current is nil. Suppose it is desired to take work off machine C, and put in D in its place. First, the horizontal bar of D is connected by screw plugs to all the vertical bars through which C is working, and machine D is started running. Next, by the double switch machine D is connected to its horizontal bar through the resistance of three ohms. Then the indicator is watched, and as the speed of D rises the current passing back from the system of conductors through D will diminish; at the moment when it is nil the resistance is short-circuited by the same double switch, thereby connecting D direct to its bar. Machine C is now slowed down, and at the moment when its current is shown by its indicator to be nil it is switched out, and the change is completed. The machines may each be run at the pressures suited to the feeders with which they are connected.

On the five-wire distributor-board there are six sliding glass plates with holes through them, two holes in each plate, for ensuring that it shall be impossible to put plugs into wrong places, and for preventing thereby the serious consequences which would follow such a mistake.

Engines and Dynamos.

In the first instance six engines and six dynamos of about 100 h.p. each were put up, and also four engines and four dynamos of 400 h.p. each. The six smaller dynamos give nearly 600 amperes at a little over 100 volts; the four larger give 600 amperes at a little over 400 volts. The engines are all vertical compound condensing, and drive their respective dynamos by link belts carried under jockey pulleys. The jockey pulleys works in every respect as well as simple belts of adequate length, and the loss of power is increased to only a very small extent, if at all. Compared with ordinary belt driving, the saving in space is considerable. In comparison with high-speed direct driving there is the advantage of entire freedom as to speed both of engines and of dynamos, and there is less liability to vibration. On the other hand, high-speed engines takes less space, and the author thinks if single acting they make less noise. In his opinion there is no great balance of advantage in one system over the other.

The condensers are ejector condensers, the condensing water being lifted some 30ft. in order to give an adequate head. These condensers have been found effective, giving a vacuum of 25in., and they prove most convenient. The regulation of electric pressure is effected by adjustment of the governor whilst running. Two more engines and dynamos of 400 h.p., exactly like those already erected, have been ordered after the experience of last winter.

Boilers.

The boilers are of Lancashire type, 30ft. long and 8ft. diameter; at present they are six in number, and a seventh is now being added. They work at a pressure of 125lb. per square inch, and are fitted with mechanical stokers, and the water is heated by economisers. The steam-pipes, feed-pipes, valves, and economisers are all in duplicate. The boiler-house, 77ft. long by 70ft. wide, is covered from end to end by a steel water-tank, weighing about 160 tons, constructed in seven compartments, and holding 205,000 gallons of water. In addition to the engines already on order, there is room for eight more large engines and five additional boilers. Hitherto no accumulators have been used; but in the author's opinion the present reduced price of these and their increased durability justify their introduction into large stations as well as small. There will, of course, be no difficulty in adding them when it is desired.

Conclusion.

There are connected to the mains 18,600 incandescent lamps of 16 c.p., 250 arc lamps, and motors to the extent of 16 h.p. This is an encouraging result when it is remembered that a preliminary supply on the two-wire system was begun only just a year ago. The average price to the consumer up to March 31 was about 5½d. per unit.

In conclusion, the author wishes to express his thanks to three gentlemen who have contributed much to the substantial success of the undertaking—namely, to Alderman Lloyd Higginbottom, the able mechanical engineer and vice-chairman of the Electric Lighting Sub-Committee, for his constant advice in all matters, whether engineering or commercial; to Mr. Charles Hopkinson, who designed the buildings; and to Mr. C. H. Wordingham, formerly the author's assistant, and now engineer of the station. He has also been not a little indebted to some of those who have contracted for the work; but they are many, and it would be invidious to distinguish.

THE HISTORY OF WOODHOUSE AND RAWSON UNITED, LIMITED,

As Detailed in the Bankruptcy Court.

The public examination of the directors and officers of this Company was continued on Friday last before Mr. Registrar Hood at Bankruptcy-buildings, Carey-street, Lincoln's-inn.

Mr. H. G. Rawson stated, with reference to the evidence given at a former sitting, that Sir Rawson W. Rawson became aware of his son's (Mr. F. L Rawson's) connection with the Phœnix Trust in September, 1890. There was no suggestion that when Mr. F. L. Rawson surrendered 25 shares held by him in the trust to the United Company, pressure had been brought upon him; the act was purely a voluntary one.

Mr. Registrar Hood said that was his impression of the evidence.

Mr. F. L. Rawson, recalled, stated that in the balance-sheet of 1891 a sum of £2,640 was included as "surplus assets on the Kidsgrove purchase." An amount of £1,000 was included in respect of the same in 1890. These sums represented the value which was placed on the stock and plant at Kidsgrove by the manager of the business, beyond the valuation of the vendors. It now appeared that a report upon that branch was made by the auditors who prepared the balance-sheet, in which it was submitted that the sum ought not to be included. So far as witness was aware that report had never been before the directors, and it did not come to his knowledge until after the winding-up order. The report ought to have been laid before the Board.

Mr. Stutchbury, who acted as secretary of the Company at the date of the report, said that he had some recollection of seeing the report. No record of it was in the minutes. He could not say whether the report was brought to the notice of the Board.

By **Mr. Jenkins**: Witness did not suggest that the minutes had been tampered with. It was his duty to write out the minutes, but they were always revised and altered by the managing director

Digitized by Google

and the chairman of the Company. Witness did not always look at the revised minutes. He did not suggest that any alterations were made in his minutes which would amount to misrepresentations as to what actually took place at the Board meetings

Mr. F. L. Rawson further stated he was certain that he did not see the report in October, 1891. In the printed balance-sheet which was laid before the shareholders on December 22, 1892, a sum of £17,784 was written off as loss on the Kidsgrove works. The report of the auditors showed a loss in 1891 of £11,000, and if the report had been received by witness it would have been laid before the directors. There was no reference to the losses at Kidsgrove in the directors' report to the shareholders in 1891, neither was there any statement that a profit had been made. At the meeting, the chairman (Sir Rawson W. Rawson) said that the directors hoped to establish a sound and profitable business, so that the shareholders could not have been led to believe that the Kidsgrove works had made a profit. On November 16 it was resolved to inform the managers of the various concerns that more care ought to be exercised in the Company's transactions, forwarding at the same time copies of the various accounts. The accounts showing the loss on the Kidsgrove business could not have been sent out because the directors were not aware of their existence. Questioned as to the Company's dealings with the Phœnix Trust, witness said that 25 founders' shares of £1 each were acquired. In the balance-sheet of 1891 they were valued at £15,000. Dividends and cash to the amount of £6,625 had been received from the trust, and shares in the Elmore companies were also transferred. The United Company had shared with the trust the profits derived from the promotion of companies. A profit of £5,600 was taken into the books of the Company in connection with the promotion of the French Elmore Company, the shares being subsequently sold for the like amount. A sum of £15,588 had been charged as profit in connection with the Elmore companies, and up to the present time only the £5,600 mentioned had been realised, the other shares not having been disposed of. One of the companies had been in existence for three years, and had not yet paid a dividend.

The **Official Receiver**: I think companies generally pay a dividend the first year.

Witness said that was not always the case. Out of a sum of £36,658 included as profit about £27,000 had not yet been realised.

The **Official Receiver**: Having regard to the large amount of profit made on paper, what explanation do you give for increasing the value of the shares in the Phœnix Trust from £25 to £15,000?

Witness said that when the Board was considering the value of these shares an offer had been made of £10,000 for the shares.

The **Registrar**: Who made the offer?

Witness said that Baron Grant was anxious to obtain shares in the trust, and offered £10,000 for them. The directors, however, thought that if the shares were worth £10,000 to Baron Grant they were certainly of more value to the Company, and therefore the offer was refused. An investigation was made into the position of the trust, and as to what the Company would receive in respect of their share of the assets if the trust was wound up It was ascertained that the Company's interest amounted to about £17,000, which was taken in the balance sheet at £15,000. This sum represented almost entirely Elmore securities, which witness believed to be of that value. With reference to the return of the dividend guarantee fund, witness stated that a rebate of £12,000 was allowed on £73,000, 18 months in advance, the balance being paid in debentures and cash. The Company had to borrow money at 7 per cent. interest to provide for the payment of the cash, the interest amounting altogether to £3,660. Witness next entered into an elaborate statement with reference to his justification for the inclusion of a profit of £35,000 in connection with the Epstein Company. He said that the United Company had expended £30,000 for the purpose of working out the patent. He did not consider that the profit was so large, having regard to the money and labour spent upon the patent. With reference to the sum of £37,000 included in the balance-sheet of 1891, witness denied that it was included with the idea of his receiving commission upon it.

Some further evidence having been given, the enquiry was adjourned until August 6.

THE ELECTRIC LIGHTING OF THE VICTORIA EMBANKMENT AND BRIDGES.

THE CAPITAL EXPENDITURE.

A report by the Highways Committee was presented to the London County Council on this subject on Tuesday. The committee stated that when they brought up a report to the Council in June, 1892, recommending the establishment of an electric installation for the lighting of the carriageway, footways, and parapet walls of the Victoria-embankment, they observed that they were advised that the capital expenditure would probably not exceed £10 000, while the cost of maintenance, including depreciation, repair, interest on capital, and ample provision for labour, would probably not exceed £2,000 per annum. The Council on June 28, 1892, adopted the recommendation, and at the same time instructed the committee to confer with the Bridges and Parks Committees respectively, and to report whether the plant could be established on a sufficient scale to enable Westminster and Waterloo Bridges and the embankment gardens to be lighted from the same source. The Council subsequently, on November 1 of that year, decided to seek parliamentary sanction for the carrying out of the installation for all these places, and powers were obtained for the purpose in the London County Council (General Powers) Act, 1893. The addition to the initial scheme submitted by the committee necessarily involved additional capital expenditure, and in the Council's Money Bill of 1893 £15,000 was provided for the purpose of establishing the installation.

In submitting their scheme on June 28, 1892, the committee stated that it was proposed that lamps of from 1,000 c.p. to 1,200 c.p. should be placed in the centre of the carriageway at about 50 yards from each other; that about 50 of these lamps would be required; and that the supply of electric light might be extended to the existing lamps on the parapet walls, and, where necessary, to those on the footways. A proposal then made to refer back this recommendation for further consideration, especially on the point of the distribution of the lamps, was not adopted by the Council; but on March 13, 1894, the views of the Council appear to have changed, for by resolution it expressed the opinion that it was undesirable to place any columns for the purpose of electric lighting along the centre of the embankment.

This resolution involved a reconsideration of the whole of the scheme; and the committee are now informed that instead of a total number of 108 lamps as originally anticipated, by the adoption of side lighting 136 will be required, an increase of more than 25 per cent. A further consequence of the resolution is that the cost of the buildings and of the boilers and machinery will also be more than anticipated. Moreover, the period for the repayment of loan has been reduced from 40 years, upon which the committee calculated as regards the more substantial part of the undertaking, to 25 years for the whole. The original and revised estimates for the installation for the embankment and the two bridges are as follow: capital cost for original estimate for 108 lamps, £15,000; revised estimate for 136 lamps, £20,000; the maintenance would be respectively £3,010 and £3,880.

The committee state that the cost of the gas lighting is about £1 800 a year, but in this amount nothing is included for interest on or repayment of loan, nor for depreciation with respect of gas lamps and mains, information as to which cannot be obtained. It is evident from the figures stated above, the committee observe, that any comparison of the relative cost of the electric light as against that of gas lighting is necessarily unfavourable to the former; but on the other hand they point out that the illuminating power of the electric light is so very much greater, and the importance to the community of a magnificent thoroughfare like the Victoria-embankment being properly and efficiently lighted is so obvious, that the extra expenditure appears to be fully justifiable.

The committee are assured that the revised estimate given above is fully adequate, and that, unless any special and unforeseen circumstances arise the Council will not have to be asked to incur any capital expenditure beyond the £20 000, the amount of the revised estimate. As above stated, the original estimate was £15,000, and it will be necessary to supplement this with a further sum of £5,000. The committee accordingly recommend that, subject to a supplemental estimate of £5,000 being submitted to the Council by the Finance Committee, the authorised capital expenditure in connection with the electric light installation for the Victoria-embankment and gardens and Waterloo and Westminster Bridges, be increased from £15,000 to £20,000. The consideration of this report was deferred by the County Council until next spring.

The Designs for Lamp Standards.

The Council, on July 10 last, instructed the committee to take the necessary measures for obtaining designs for the electric lamp standards to be erected on the Victoria-embankment, and to advise the Council what premium should be offered for the best design. Having given full consideration to the matter, they are of opinion that the premium should be 25 guineas. As soon as the Council have decided the amount of the premium, the committee will proceed to invite competitive designs, and they propose to consider later on the question as to what arrangements shall be made for carrying out the Council's resolution. They recommend, therefore, that £26. 5s. be the amount of the premium to be offered for the best design for electric lamp standards.

Generating Station Buildings.

The committee have considered the two tenders opened by the Council on July 10 last for the erection of the generating station buildings for the electric light installation. The lower is that of Messrs. Foster and Dicksee, who offer to do the work for the sum of £5,562, and the committee think that their tender should be accepted. They accordingly recommend that the tender of Messrs. Foster and Dicksee be accepted, that the solicitor be instructed to prepare a contract to give effect to the tender, and that the seal of the Council be attached to the contract when ready. This recommendation was also postponed until next spring.

Plant for Generating Station.

The Council on Tuesday opened the tenders received for the supply of engines, dynamos, switchboards, etc., and boilers, condensers, pumps, etc., required for the generating station. Owing to the delay which must necessarily occur in obtaining the designs for the lamp standards, and afterwards the requisite supply of standards according to the selected design, it will not be possible to fully light before next winter the embankment and gardens by means of the installation; but the committee are endeavouring to arrange for the electric lighting of the bridges and of the parapet wall of the embankment before that time. In order therefore that there may be no unnecessary delay in consequence of the vacation, the committee recommend that the tenders,

Digitized by Google

which are given in another column, be referred to the Highways Committee with authority to accept the tenders which it may consider most advantageous to the Council, and to enter into contracts on behalf of the Council.

MAINS AND LAMPS.

The committee think it advisable that contracts should be entered into at as early a date as possible for the supply and laying of the mains, and for the supply of the electric lamps to be placed in the lanterns. They therefore recommend that the Highways Committee be authorised to invite tenders, and to enter into contracts on behalf of the Council for the supply and laying of the mains, and the supply of the electric lamps required for the installation.

THE CITY COMMISSION OF SEWERS AND TELEPHONE TUBES.

In our issue of 20th ult. we referred to the discussion which took place at a meeting of the City Commission of Sewers during that week on the subject of the telephone tubes laid down by the City of London Electric Lighting Company.

On Tuesday the matter again came up, when **Mr. Pannell** moved the following resolution, which stood on the agenda paper in his name: "That the resolution of this Court of July 25, 1893, agreeing to a recommendation of the Streets Committee, that the Commissioners only consent to the use for telephonic purposes of certain tubes laid by the City of London Electric Lighting Company, on a guarantee being given that telephones with double wires and all the latest improvements will be supplied to the citizens at a cost not exceeding £8 per annum, be rescinded." Mr. Pannell said he would not have brought forward the motion had it not been for a remark dropped at the last meeting by an hon. member which he thought was extremely pertinent. The member to whom he referred said no committee or section of the Commission could deal with any negotiations in regard to the question while the existing resolution appeared on the minutes of the Court. He (Mr. Pannell) agreed that the present position in which the Court was placed was a very undesirable one. The tubes which had been the subject of dispute were underground, and they represented a capital of between £80,000 and £100,000. The Commission had received an offer whereby the rates could be benefited, while it was possible also that the users of telephones would be the recipients of benefits, but as long as the present block existed the Court was simply playing into the hands of the National Telephone Company. That company, Mr. Pannell proceeded to observe, were wise enough to secure the new company which was started first and was called the New Telephone Company. The former company had indeed absorbed the latter together with the contract for the leasing of the tubes in question. He ventured to say that it was now most advisable to put an end to the present state of affairs, and this could be accomplished without any sacrifice on the part of the Commission. Mr. Pannell said he would not venture to suggest any form or arrangement by which the ratepayers might hereafter benefit, or by which the users of telephones in the City would reap an advantage, but it was only right that the Commission should have the means of carrying on negotiations in the future, and that the Court should be removed from the present difficult and impossible position. The object of his motion was simply to clear the ground, and in his opinion the ground should be cleared as speedily as possible.

Mr. Sayer having seconded the motion, and expressed his concurrence with the views of the mover,

Mr. Morton expressed his regret that the remark which he made at the last Court should have had the effect of inducing Mr. Pannell to place the present resolution on the agenda. He urged the Court to wait until the agreement between the Government and the National Telephone Company was placed, as it would be in a few days, on the table of the House of Commons. He declared that the whole secret of the business was that the electric lighting company sought to benefit by the present state of things, and he contended that the honour of the Commission was concerned in the present dispute.

Mr. Burmester, in protesting against Mr. Morton's imputations, remarked that it might be said that the hon. member held a brief for the telephone users. He agreed with him, however, that the honour of the Commission was involved, but it was concerned in the protection not of one section of the ratepayers but of the entire body.

Mr. McCarthy having expressed himself in favour of the motion,

Mr. C. T. Harris opposed the proposition. The Court could, he said, rescind the former resolution whenever a fair proposition was submitted to it. He was opposed to playing into the hands of the National Telephone Company as much as he was opposed to playing into the hands of the electric lighting company.

Mr. Alderman Green denounced the continuation of the present dog-in-the-manger policy, and contended that the time had arrived when the resolution in question should be rescinded.

Mr. Pannell, in reply, said if the resolution was carried, as he hoped it would be, by a two-thirds majority, and the National Telephone Company did not come to bid, another would soon be found to do so, and an end being put to a monopoly, cheaper telephone communication would be secured.

On a show of hands the motion was supported by 33 votes, and there were 16 against it. On a division the numbers were 32 for and 14 against.

The necessary majority having been obtained, the motion wa declared by the **Chairman** to have been carried.

COMPANIES' REPORTS.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

Report of the directors and abstract of accounts for the half-year ending June 30, 1894, to be submitted to the twelfth half-yearly general meeting of the shareholders to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Tuesday, August 14, 1894, at 12 noon.

Directors: Sir William Bower Forwood, J.P., Ramleh, Blundellsands; James Barrow, Esq., J.P., 7, Beach-lawn, Waterloo; John Brancker, Esq., J.P., Green Bank, Wavertree; Harold Brocklebank, Esq., 20, Bixteth street, Liverpool; Richard Hobson, Esq., J P., 54, Brown's-buildings, Liverpool; Edward Lawrence, Esq., J.P., 5, Fenwick-street, Liverpool; George H. Robertson, Esq., K 35, Exchange-buildings, Liverpool. Engineers-in-chief: Sir Douglas Fox, M.I.C.E; J. H. Greathead, Esq., M.I.C.E. Engineer and manager: S. B. Cottrell, Esq., A.M.I.C.E., 31, James-street, Liverpool. Secretary: William H. Alexander, Esq., C.A., 24, North John-street, Liverpool.

In presenting the half-yearly statement of capital and revenue accounts to June 30, 1894, your directors have to report that the gross revenue receipts amount to £20,044. 7s. 6d. The number of passengers carried since the opening of the railway being as follows:

	From March 6 to June 30. 1893.	Half-year ending Dec. 31, 1893.	Half-year ending June 30, 1894.
First class	235,487	260,221	277,653
Second class	956,922	1,293,840	1,246,975
Workmen (special return tickets)	178,333	921,578	1,336,809
Total	1,370,742	2,475,639	2,861,437

During the past half-year 50,483 trains have been run, and 96 per cent. have been punctual. The northern extension was opened on April 30, and the traffic at the Seaforth Sands Station has been very satisfactory. An arrangement has been made with the Liverpool Tramway and Omnibus Company to run omnibuses to this station, connecting it with the surrounding districts, and generally to act as feeders to the railway. Two new stations have been opened this month at points where experience has shown it to be desirable to provide further accommodation—viz., at Nelson and Huskisson Docks—and a third will shortly be opened at Langton Dock.

Revenue Account.

The gross receipts from traffic amount to	£19,658 13 11	
Miscellaneous receipts	385 13 7	
	£20,044 7 6	
Less working expenses	14,947 5 6	
	£5,097 2 0	
From which deduct—		
Interest on debentures and calls paid in advance ..	2,639 7 7	
	£2,457 14 5	
Add balance brought forward from last year	2,598 7 1	
Leaving available for dividend the sum of	£5,056 1 6	

Out of this balance your directors recommend the declaration of dividends at the following rates (less income tax), payable on and after August 17—viz.: 5 per cent. per annum on preference shares, £2,170. 13s. 8d.; 1 per cent. per annum on ordinary shares, £1,875; total, £4,045. 13s. 8d.; leaving a balance of £1,010. 7s. 10d. to be carried forward to next half-year.

REVENUE ACCOUNT, HALF-YEAR ENDED JUNE 30, 1894.

Half-year ended Dec. 31, 1893.	Expenditure.	£ s. d.

COMPANIES' MEETINGS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

The twentieth ordinary general meeting of the shareholders was held at Winchester House on Wednesday, Mr. Charles Grey Mott presiding.

In moving the adoption of the report, which we printed in our last issue, the **Chairman** stated that during the past half-year they had carried 236,498 passengers more than in the corresponding period of last year, and the number of season-ticket holders had increased by 49. This increase had been carried with the usual perfect safety, and almost absolute punctuality. The increase had been obtained in spite of the fact that the Oval was shut for football matches during the first three months. They had now got the railway in all its main details into thorough working order, and the directors had turned their attention to smaller details in order to make the line draw better. The King William-street Station had been improved on the surface, and this expenditure was not only likely to be remunerative by making it more attractive to passengers, but also directly from the receipts of the new left-luggage office, which could be used not only by their own travellers, but also by the general public crossing London Bridge. They were also trying to improve the carriages, and had a new train running with more ease and with less noise. They were considering the question whether the locomotives could not be abolished, and motors on the trains themselves be substituted. This had been the first idea when the line was projected, but in deference to the views of the Board of Trade it had not been carried out. The suggested method would allow of an additional carriage being added to each train. They were trying experiments, but owing to the smallness of the tunnel and to other reasons it was dubious if the arrangement could be made. Turning to the accounts, it would be seen that during the half-year 8,200 of the terminable mortgage debenture bonds had been paid off and reissued as debenture stock, or preference shares, at a premium; and the loan of £22,000, to which reference was made at the last half-yearly meeting, had been repaid. The receipts from all sources for the six months had amounted to £24,294, and the cost of working had been £14,990, leaving a profit of £9,304. Inclusive of the balance brought forward from December 31 last, the net revenue account showed an aggregate total of £10,368. After making provision for the debenture and debenture stock interest, there remained a balance of £6,295 available for dividend. The total working expenses for the half-year had been reduced to 61·7 per cent., against 64 61 at that time last year. If they took into account the cost of working the lifts, which did not properly belong to a railway, the percentage worked out at about 52 per cent., which was considerably lower than that of many of the large English railways. The receipts per train mile had been 2s. 1½d., and the receipts per passenger 1·62d.—practically the same as in the corresponding half-year. The locomotive expenses per train mile had been 6·21d. against 6·48d. in 1893. Although the dividend was not as large as he would like to see, the Company was making steady, though not rapid, progress. There was not much hope of rapid progress, and they would have to be content with a slow movement upwards with the present materials at command, and no extension of the line.

Mr. Sampson Hanbury seconded the adoption of the report.

Mr. Drake said that it had been unquestionably demonstrated that electricity could be practically used for motive power, and also that the line was useful to South Londoners, but the remaining point still to be demonstrated was that it should return a fair interest to the ordinary shareholders. At present the traffic was throttled at King William-street. If they were once relieved there, and the original project carried out, there would be a reward to the people who had put money into the line.

Mr. Shepherd stated that there was no reference in the report to any extension of the line. A continuation to Moorgate-street was needed, and would be of benefit.

Mr. J. P. Court stated that every £400 of increase in the profits meant ¼ per cent. extra dividend on the ordinary stock. There should consequently be more economy in the general charges. The managerial expenses amounted to £3,000, and the whole management was on too magnificent a scale. This was not a railway, but a tramway with 3½ miles of line. The offices of manager and secretary could be combined, and result in an increase of ⅛ per cent. on the ordinary shares. He concluded by giving notice that at the next half-yearly meeting he would move the reduction of the directors' fees from £1,300 to £750 per annum.

Mr. Middleton said that it had been promised him at the last meeting that experiments would be made with motors on the carriages, and that the engineer would report on the effect. This was not forthcoming, and the shareholders were now met with the statement that experiments were to be made. The dividend might have been increased to 1½ per cent. by carrying less forward in the balance. As regarded the Moorgate-street extension, he considered that there should be no extension until at least 2 per cent. dividend was paid. More economical working was required, and the staff was far too large. Any extension should be carried out as a separate undertaking, and he would strenuously oppose the raising of debenture capital for such a scheme.

The **Chairman**, in reply, said that Mr. Middleton did not understand the working of a railway line like this or appreciate the difficulties. The speaker had from the first favoured motor cars, and they had given orders to two firms so as to expedite the matter. They had no plans yet for extension, but the completion of the line to Moorgate-street would result in an almost immediate increase of the dividend to 5 per cent.

The motion was then carried.

The **Chairman** moved, and **Mr. Greathead** seconded, the motion that 1 per cent. dividend be paid on the ordinary stock, which was agreed to.

MANCHESTER EDISON-SWAN COMPANY, LIMITED.

The twelfth ordinary general meeting of this Company was held on Monday at the Memorial Hall, Albert-square, Mr. V. K. Armitage, chairman of the Company, presiding.

The directors' report, which was taken as read, was as follows: "The net profit, including last year's balance, amounts to £1,508. 17s. 5d., which it is proposed to appropriate as follows: to writing off balance of loss on Williamson Electrical Engineering Company, £940. 0s. 1d.; to special depreciation owing to change of showrooms, £256. 5s. 6d.; to special depreciation on stock of lamps on

Digitized by Google

expiration of patents, and to reduction in value of cables, £306. 11s. 5d.; balance to be carried forward, £6. 0s. 5d. The directors view the result of the year's trading as satisfactory, considering the depressed state of trade during the last 12 months, and the fact that the Company's monopoly of the lamp trade has now ceased They propose to write off the whole of the loss made on the Williamson Electrical Engineering Company, Limited, and the special depreciation shown above this year, and accordingly do not recommend the payment of a dividend."

The **Chairman**, in moving the adoption of the report, referred to the work that has been undertaken at Altrincham and Bowdon, and said he thought that from that installation the shareholders were justified in expecting a satisfactory financial result. He believed that in that and in other directions the future of the Company was hopeful.

Mr. F. B. Ross seconded the motion, which was adopted.

Mr. F. B. Ross and Mr. W. P. James Fawcus were re-elected directors.

ANGLO-AMERICAN TELEGRAPH COMPANY, LIMITED.

The ordinary half-yearly meeting was held last week at the Cannon street Hotel, the Marquis of Tweeddale presiding.

The **Chairman**, in moving the adoption of the report, stated that the traffic receipts for the half-year had been £130,094, showing a diminution of £16,791. They now had four cables across the Atlantic in first-class order, and they were all duplexed. The fifth cable, the French cable, they had not attempted to repair this year, nor did he think there was any probability of that repair being undertaken this year. The expenses of the new cable and of the repair of the 1874 cable had made serious inroads into their renewal funds, which would be reduced to about £530,000. The amount they proposed to set apart to this fund—£12,000 each half-year and the interest earned by the fund—was a minimum figure. Judgment had at length been given in their favour in the proceedings with regard to the Pouyer-Quertier cable. The judgment at any rate proved that their contention was correct, that the French company committed a serious breach of their agreement, but whether the result of the decision would be attended with any great financial benefit to the "pool" companies was doubtful, for it was impossible to express an opinion as to what view would be taken by the experts by whom the damages were to be assessed. No doubt they had heard with some dismay of the possibility of one or two more cables being laid in the Atlantic. It was said that the French were contemplating the laying of a new cable, but of this they possessed no reliable information. They had reason, however, to believe that the German Government contemplated giving a concession for a new cable from Germany to America. He only hoped that it would fall into the hands of those who had large interests in the "pool" companies, instead of into the hands of hostile competitors.

Mr. Francis A. Bevan (the deputy-chairman) seconded the motion, which was carried.

GLOBE TELEGRAPH AND TRUST COMPANY, LIMITED.

The ordinary general meeting was held last week at Winchester House, under the presidency of Sir John Pender, M.P.

The **Chairman**, in moving the adoption of the report and the payment of the dividends recommended, stated that the receipts for the year ended the 18th July, after paying all expenses, had been £185,057, as against £188,931 in the previous year. The object of the Globe Company was to equalise the dividends paid by the various telegraph companies in which they held investments, and this object, to a very large extent, had been attained. They were able to recommend the payment of a dividend on the ordinary shares of 4½ per cent. for the year, or ⅛ per cent. less than in the previous year. The dividend they were paying was still above the average, and taking their preference and ordinary shares in like quantities, they showed a return of 5¼ per cent. He then referred to the dividends which they had received from their investments in the Anglo American Telegraph Company, the Direct United States Cable Company, the Submarine Cables Trust, and the Telegraph Construction and Maintenance Company, and afterwards stated that the £62,000 which they had held in 6 per cent. debentures of the Direct Spanish Telegraph Company was paid off last May. The money had been since reinvested. With reference to the West Coast of America Company, now that the Transandine line was completed, they might possibly get some return from that company.

The **Marquis of Tweeddale** seconded the motion, which was adopted.

CHILI TELEPHONE COMPANY, LIMITED.

The annual general meeting was held on Tuesday at Winchester House, Mr. Thomas Greenwood presiding.

The **Chairman**, in moving the adoption of the report, said the year through which they had just passed had been the worst that the Company had seen, and he thought he might fairly add the worst it was likely to see. In consequence of the low price of the dollar, the Board had felt compelled to make a small addition to their tariff. This had had the effect of causing some of their subscribers to withdraw, but others had taken their places, so that the aggregate in all centres was, at the end of the year, only 37 less than at its commencement. Although they had been so long without a dividend, he felt their prospects were hopeful.

The **Hon. F. Ernest Allsopp** seconded the resolution, which was adopted.

CONTRACTS FOR ELECTRICAL PLANT.

CONTRACTS OPEN.

Maidstone.—The Town Council are still desirous of receiving particulars as to the terms on which a company or firm will undertake and carry out the powers granted by the Maidstone electric lighting order.

Cheshunt.—The Local Board invite tenders for the public lighting of the district by gas, oil, or otherwise. Specification, stating period of lighting and district to be lighted, may be seen at the office of Mr. S. Towlson, the surveyor to the Board, Turner's-hill, Cheshunt. Tenders are to be sent, addressed the Chairman, Cheshunt Local Board, St. Mary's Hall, Cheshunt, by the 6th inst.

St. Pancras.—The St. Pancras Vestry, as will be seen from our advertisement columns, invite tenders for the supply and laying of armoured cable mains. Specifications, schedules of quantities, general conditions, and plan of streets can be obtained at the offices of Prof. Henry Robinson, 13, Victoria-street, Westminster, on payment of 5s. Tenders must be sent in by 16th inst. to Mr. Albert E. Pycraft, chief clerk, Vestry Hall, Pancras-road, N.W.

RESULTS OF TENDERS.

West Ham.—The following tenders were received by the Corporation of West Ham for the electric lighting of the public hall and library at Canning Town :

	General lighting.	Extra power for blowing organ.	Extra for footlights on stage.	Total.
Fanshawe and Grant	£839 0 0	£60 0 0	£18 0 0	£917 0 0

Digitized by Google

The tender of the Brush Electrical Engineering Company has been accepted.

Bury.—The Board of Guardians are to enter into a contract with Messrs. E. Green and Son, Limited, for the supply of a fuel economiser.

Woking.—The Local Board, as will be seen in another column, have accepted the tender of Messrs. New and Mayne for the electric lighting of Woking Station and Maybury Ward.

London.—The tender of Messrs. Graham and Biddle, of 463, Oxford-street, W., has been accepted, at £534, for the installation of the electric light for Mr. J. H. Renton, 39, Park-lane, W. Mr. W. J. Fryer, A.I.E.E., was the consulting engineer. The same firm's tender has been accepted for installing the electric light and for organ-blowing apparatus by electric motor by the wardens of the West London Synagogue, Upper Berkeley-street, W. Mr. Fryer also acted as consulting engineer in this case. The amount of the tender was £189; two other firms offered to do the work. Another contract secured by the same firm is for the electric lighting of 34, Bryanstone-square, W., for Mr. Francis Samuels, the tender reaching the sum of £445.

London (County Council).—The following tenders have been received by the London County Council in connection with the electric lighting of the Victoria-embankment:

For the supply of engines and electrical plant.

Laing, Wharton, and Down, 82A, New Bond-street	£12,100
W. Mackie, Turk's Head-yard, Turnmill-street, E.C.	8,880
T. Scott Anderson, Royal Insurance-buildings, Sheffield	5,660
Brush Electrical Engineering Company, Limited, 49, Queen Victoria-street, E.C.	5,437
C. A. Parsons and Co., Heaton Works, Newcastle	5,471
Johnson and Phillips, 14, Union-court, E.C.	5,200
Paterson and Cooper, Pownall-road, Dalston	5,000
J. G. Statter and Co., Limited, 68, Victoria-street, S.W.	4,629
Greenwood and Batley, Limited, Albion Works, Leeds	4,565
Crompton and Co., Limited, 4, Mansion House-buildings, E.C.	4,444
Electric Construction Company, Limited, Wolverhampton	4,410

For the supply of boilers, etc.

Spurr, Inman, and Co., Limited, Calder Vale Boiler Works, Wakefield	3,375
Maudslay, Sons, and Field, Limited, Westminster Bridge road	2,765
Babcock and Wilcox, Limited, 147, Queen Victoria-street, E.C.	2,554
Yates and Thom, Canal Foundry, Blackburn	2,436
J. Watt and Co., 90, Leadenhall-street	2,450
Standard Ironworks, Colchester	1,403
Davey, Paxman, and Co. (informal)	—

The Highways Committee on Tuesday recommended that the tender of Messrs. Foster and Dicksee, at £5,562, should be accepted for the erection of the generating station buildings for the electric lighting of the Victoria-embankment, but this was deferred until next spring.

BUSINESS NOTES.

Chelsea.—The Town Hall is nearly ready for the electric light.

Coupar-Angus.—The electric light is to be introduced at Jordanston House.

Carlow.—The Town Commissioners have decided to erect additional electric lamps.

Wolverhampton.—A proposal is under consideration for the electric lighting of the workhouse.

Western and Brazilian Telegraph Company.—The receipts for the week ended July 27 were £2,162.

Sunderland.—The question of wiring the Town Hall is under the consideration of the Town Hall Committee.

Bristol Tramways.—The proposed electric tramways to St. George and Kingswood are expected to be set in operation next year.

St. Helens.—The Corporation have obtained powers to supply electricity, and have appointed Mr. R. Hammond to draw a report and submit estimate of works.

Poplar, E.—The report prepared by Mr. W. H. Farnfield in regard to street lighting by electricity is to be printed for the Poplar District Board of Works.

Norwich.—Extensions are being made in the central station by Messrs. Laurence, Scott, and Co., and at present some 12,000 8-c.p. lamps are connected to the mains.

Heston and Isleworth.—The Local Board have accepted the estimate of Mr. Stewart at £22. 10s. for the alteration of the telephone system between the fire stations.

Portsmouth.—The Library and Museums Committee of the Town Council have decided to purchase an electric motor of 5 h.p. for the technical institute, at a cost of about £55.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 29th ult. amounted to £933, as against £724 in the corresponding week of last year.

Heysham.—The Lancaster Rural Sanitary Authority have consented to the electric light company applying to the Board of Trade for a license to supply electricity to Heysham.

Hardwick's "Purine" Syndicate, Limited.—This Company has been registered, with a capital of £1,000, to carry on the business of bankers, capitalists, civil, mechanical, and electrical engineers, etc.

Cabul.—The *Dundee Advertiser* states that the Ameer has decided to introduce the electric light into his capital, and Mr. R Jamieson Browne, a Glasgow electrician, has been asked to fit up the installation.

Church-Lighting.—Owing to the delay in the supply to the Leeds House-to-House Company of a part of the plant ordered by them, the installation of electric light at the parish church will only be partially at work next Sunday.

Mansion-Lighting.—Lord Rosebery has taken Eastwell Park, the Kentish residence of Lord Gerald, for a term of three years. Extensive improvements will, it is stated, be made to the mansion, including the installation of the electric light.

Barrow.—The General Purposes Committee of the County Council have reported, in regard to the application for provisional order, that the Commons have agreed to the Lords' amendments, and that the Bill had received the Royal assent.

Tunbridge Wells.—The Local Government Board have sanctioned the borrowing by the Town Council of £13,000 for electric lighting purposes. Messrs. Longley and Co., of Crawley, are going to erect the station buildings for £2,789.

Wickham Market.—A Vestry meeting held at the White Hart Hotel, Wickham Market, appointed Messrs. R. Fulcher, E. Coleman, and H. E. Morris as lighting inspectors until the Lighting and Watching Act has been adopted by the Parish Council.

The Cardiff Exhibition.—One side of the proposed buildings round the quadrangle for the forthcoming exhibition is to be devoted to machinery and electricity. It is also suggested that there be an electric railway on the western side 2,500ft long.

Aberystwyth.—The pillars of the electric arc lamps have been erected the whole length of the Marine and Victoria terraces facing the sea, numbering 17. There are 18 more to be fixed in different conspicuous positions within the borough and on the Chain Pier.

Declaration of Dividend.—The Kensington and Knightsbridge Electric Lighting Company, Limited, have declared an interim dividend at the rate of 5 per cent. per annum on the ordinary shares for the half-year ending June 30, payable on and after August 2.

Dunstable.—The Town Council have resolved, on the recommendation of the Lighting Committee, to purchase 70 lamp-posts which have been used for electric light purposes in Barnet, and which were offered to the Council by a firm at the low figure of £1. 2s. 6d.

British and Foreign Electric and Engineering Company, Limited.—This Company has been registered with a capital of £2,000 in £1 shares, to carry on the business of electric, telegraphic, surgical and scientific instrument makers, and electrical and mechanical engineers.

Hampstead.—Mr. R. A. Chattock, who has been appointed electrical engineer to the Hampstead Vestry, was the superintending engineer of the Metropolitan Electric Supply Company's Amberley-road station. A proposal is being considered for the electric lighting of the Vestry Hall.

Glasgow.—The Glasgow and South-Western Railway Company have decided not in the meantime to appoint a mechanical and electrical engineer for St. Enoch's Station, an appointment which they announced to be open some time ago. This was a new post on the railway, and a salary of £200 was offered.

City and South London Railway.—The receipts of the Company for the week ended July 29 were £858, against £824 for the corresponding week of 1893, or an increase of £34. The total receipts for the current period of the present half-year amount to £3,458, as against £3,433 in the corresponding period of 1893.

St. Luke's.—The surveyor to St. Luke's Vestry has been directed to report to the Vestry, from time to time, as the County of London and Brush Provincial Electric Lighting Company, Limited open up the thoroughfares of the parish to lay their system of lighting, with a view to the reinstatement of the paving.

Salford.—Mr. Holland, chairman of the Gas Committee, in reply to Mr. Alderman Dickins and Mr. Alderman Mottram, stated at a meeting of the Town Council on Wednesday that he could not give the price at which the electric light would be supplied. He thought the installation would be complete in time for the winter.

United River Plate Telephone Company.—The report for the year ended March 31 shows a profit, after deduction of debenture interest, of £9,782. After various deductions, including the transfer of £3,000 to depreciation and renewal fund, there is a net balance, including £905 brought forward, of £6,417, which is carried forward.

Rollason's Wind Motor Company, Limited.—A meeting of this Company was held at Winchester House yesterday afternoon, but the proceedings were private. This Company exploits a windmill driving a dynamo for electric lighting and power purposes. An illustrated description of the wind motor was given in our issue of April 20 last.

Dover.—The surveyor has reported to the Town Council that he had written to Mr. Lawson, engineer to the Dover Electric Supply Company, asking that they should send all official notices, and he had since received the official notice of the opening up of Snargate-street. He also stated that he was going to block up Snargate-street in sections during the laying of the mains.

Recovery of Gold.—Mr. Justice Romer, in the Chancery Court on Tuesday, reserved judgment in the action brought by the Cassel Gold Extracting Company, of Glasgow, for an injunction restraining the Cyanide Recovery Syndicate from an alleged infringement

Digitized by Google

of their patent for the extraction of gold from the ore by a solution of cyanide of potassium. The case was referred to in our last issue.

Greenock.—The Caledonian Electric Supply Company, Edinburgh, have intimated to the Greenock Police Board that the company intend to apply to the Board of Trade for a provisional order to supply electricity within the district area comprised within the municipal boundaries of Greenock. The town clerk has been instructed to notify the company that the Board of Police will oppose the application.

Driving Printing Machinery—The fast Victory web rotary machine which prints the *Oxford Times* is now driven by an electric motor of 10 h.p., erected by Mr. McLean, the engineer of the Oxford Electric Lighting Company. This is the first printing done in Oxford by electric power, and the satisfactory results lead to a belief that it is preferable to gas or steam, as being steadier, quieter, and more easily controlled.

Belfast.—At a meeting of the Electric Lighting Committee of the Corporation the electrical engineer (Mr. M'Cowen) reported the progress which had been made in the works since the last meeting, and submitted further applications for current from parties outside the proposed area of supply. He was instructed to proceed with the work in every case outside the area where the necessary guarantee form was signed.

Dock-Lighting.—The East and West India Company, London, have spent £12,000 (spread over certain years) upon a new electric light installation for the Albert Docks, and this has resulted in a saving during the six months of £1,000. The chairman of the company mentioned the other day that an increased use of electric travellers at the wood wharf had also led to economy, and that they intended to have more of these travellers.

Dunoon.—The first illumination of the Castle Gardens this season took place on Thursday night last week in the presence of over 3,000 people, when it was also made the occasion of the formal introduction of the electric light, which has been carried out by Messrs. Walter Dixon and Co., electrical engineers, St. Vincent-street, Glasgow. The opening ceremony was performed by Captain Howitt, convener of the Roads Committee.

Mill-Lighting.—Messrs. Bennett and Druce, of Preston, have secured the contract for an electric light installation throughout the Crosse Hall Mill of Mr. J. H. Gillett, of Chorley. The dynamo will be a 12-kilowatt machine, driven off the main mill engine, and about 200 incandescents, distributed over the spinning department, will be installed. We are informed that the firm is exceedingly busy with various installations in progress in the Lancashire district.

Town House Lighting.—Messrs. Rashleigh Phipps and Co. have received instructions from Mr. W. D. Mackenzie, of Fawley Court, Henley-on-Thames, for the electric lighting of his town house, 35, Park-street, which they are now engaged on. This firm have also received an order to light the house of Mr. Anderson Critchett, the celebrated oculist, in Harley-street They are also engaged upon a large number of other installations in London and country.

Halifax.—Sixty-three applications have been received for the supply of the electric light. The Masonic Hall Committee have decided to introduce this system of lighting into their premises. The work of building the station in Foundry-street is proceeding apace, part of the wall having already been erected. Three large boilers from a Blackburn firm have been placed in their foundations. Mr. Wilmhurst is the electrical engineer, and Mr. Rayner he clerk of the works.

Newcastle.—In connection with the lighting of this city, to which subject we have previously referred, a meeting of the Watch Committee was held on Monday. The directors of the gas company attended, and a conference took place respecting the lighting of lamps in the streets of the city. A local paper says that "the outcome of the discussion was a hopeful feeling that matters between the gas company and the Corporation might be amicably adjusted." The meeting was adjourned for further consideration of the subject in dispute.

Lighting in Pall-mall.—The Establishment Committee of the London County Council reported on Tuesday that they thought it desirable that the rooms taken at 17, Pall-mall East, for the housing branch of the architect's department, should be equipped with the electric light. The engineer estimates the cost of the mains, fittings, etc., at £65. The committee therefore recommended that, subject to an estimate being submitted to the Council by the Finance Committee, an expenditure of a sum not exceeding £65 be authorised for the purpose.

Dorby.—It was mentioned at a meeting of the Town Council on Wednesday that the electric light mains have been ordered to be extended in several places to meet the requirements of new customers, and that forty motors have been ordered, at a cost of about £300. The electric lighting exhibition in May was well patronised by the public. The cost of the exhibition to the Corporation was £76. 17s. 11d., which was less than the amount first contemplated. No charge was included in the above for current, which at the ordinary rate would be £45.

Wolverhampton.—Mr. F. Harman Lewis, the borough electrical engineer, has issued for the benefit of the inhabitants a circular which deals with the advantages of the electric light. It runs: "The electric light mains are now laid in your street, and as there is every probability that the electric light station will be in working order in September, the Corporation takes this opportunity of reminding you of the advantages to be derived from employing electricity as a source of artificial illumination. The charge for electric energy will be 6d. per Board of Trade unit."

A Contract Question.—The case of G. West and G. Batchelor *v.* the Chatham Electric Light Company and Jasper, was an action heard in the High Court. It was brought by Mr. G. West and Mr. G. Batchelor as assignees of a debt of the contractor for work done and materials supplied in connection with the electric light. The trial came on before the official referee, Mr. Verey, lasting two days. During the action defendants counterclaimed, but this was dismissed before trial. The referee has now given his judgment, whereby plaintiffs recover £74. 10s. 5d., and all costs. The original claim was over £80.

Bristol.—The Bristol Electric Lighting Committee of the Town Council met on Friday. The committee, having been informed of the replies to the circulars recently issued with reference to extending the mains to Clifton and Tyndall's Park, decided to extend the mains to Clifton forthwith. The work will be executed by the Corporation employés, and will be put in hand in about a month's time, so as to be completed by the end of September. It was decided to promote Mr. J. Rutherford Blaikie, third assistant engineer, to the post of chief assistant, and to appoint Mr. C. B. Jones-Mortimer third assistant engineer.

Hull.—The Electric Lighting Committee of the Hull Corporation received on Wednesday from Mr. Gibbings, the engineer, a report on additional plant required for the electric lighting station. A resolution was passed that it is desirable that the present plant should be increased by the addition of a large engine and dynamo, together with the requisite fittings, steam-piping, motor generator, etc., and that the orders for the same should be placed immediately. The committee, therefore, decided to recommend the Council that they should be empowered to purchase such engine and dynamo, fittings, steam-piping, motor generator, etc., at a cost not exceeding £2,800.

Edison-Bell Phonograph Company v. Hough.—The hearing of the motion for an interim injunction to restrain the defendant, who trades as the London Phonograph Company, from infringing certain rights which the plaintiffs claim to possess in a patent of 1886 for improvements in phonographs, was concluded on Tuesday before Mr. Justice Stirling. The defendant having offered to pay £25 into court, his lordship said that upon that sum being paid in, and on the parties undertaking to prosecute the action without delay, he thought there ought not to be an injunction, but that the defendants must keep the usual account. The injunction was accordingly refused, and liberty was given to either party to expedite the trial.

Dublin.—The sixty-second annual report of the Commissioners of Public Works in Ireland, covering the year ending March 31, 1894, has just been issued. During the 12 months under consideration the net expenditure under the control of the Board was £505,681. Amongst the items which have swelled this sum is the Amiens-street Parcel Post Depôt, which is now approaching completion. The Board have decided to employ electric lighting for this building, and have arranged for a supply from the municipal electrical system However, the Commissioners, being of opinion that the terms for this service are too high, have given notice to the Corporation that the present contract for the supply of electric light will not be resumed after three years.

Aberdeen.—On Monday a joint meeting of the Gas and Watching and Lighting Committees of the Town Council was held, when a discussion took place on the question of the electric lighting of the streets. It was stated that the cost of producing the current for street lighting purposes exceeded the sum formerly estimated. In view of this the committee decided to continue the present arrangements for another month, at the end of which the committee would have before them the first accounts Having then ascertained the actual cost of production the rate will be fixed accordingly. Mr. W. Kennaway has had his establishment in Union-street lighted by electricity, the work having been carried out by Mr. Walter Simpson, of Thistle-street, Aberdeen.

Bath.—The Bath Electric Light Company have secured the contract for the supply of current to Messrs. Cater, Stoffell, and Fortt's new premises in High-street, where over 100 incandescent lamps will be installed. Several other firms have also decided to adopt the electric light in preference to the Welsbach gas burners, and Messrs. Mactavish and Co. are now busy wiring Messrs. Coleby and Giles's premises, Stall-street, Grapes Inn, Westgate-street, and where further extensions are contemplated; and orders for wiring have been sent in by Mr. Hayward, Green-street, Mr. E. White, Kingsmead-square, and Mr. Ashcroft, York House Hotel. The Surveying Committee of the Town Council intend to recommend that the application of the Electric Lighting Company for an extension of their license to 21 years should be opposed.

Colliery-Lighting—The Alloa Coal Company have had their large Devon Colliery, at Sauchie, near Alloa, lighted by electricity. There are two dynamos driven off their large fan engine on the surface. The installation consists of four 2,000 candle arc lamps, suspended on poles 40ft. long, embracing the surroundings of the pit-head, while the different engine-rooms, screens, pit-head, workshops, and offices are lit by 16 and 50 candle lamps. Main cables are carried down the air shaft, and the whole of the pit bottom, haulage and hydraulic engine rooms, stables, and main roads are likewise fitted up with incandescent lamps, doing away with all naked oil lamps formerly in use. The company's Bannockburn Colliery is also fitted with the electric light. Both installations were carried out by Messrs. Thomas Laurie and Co., electrical engineers, of Falkirk.

Ulverston.—The Rural Sanitary Authority, as mentioned in a previous issue, have received notice of the intention of the Windermere and District Electric Light Supply Company to apply

Digitized by Google

to the Board of Trade for a provisional order enabling the company to supply electricity within the Authority's district. At a recent meeting of the Authority, Mr. Hodgson moved that a small committee should be appointed to consider the letter and report. If the order to be asked for were granted, it would give the company a complete monopoly of electric lighting in the Authority's district. It was proposed to utilise the power of the Leven, and works were to be erected on the banks of that river for the development and distribution of electricity. This might be very beneficial in some cases, but an order to apply to the whole district would be a very sweeping matter, and would, for instance, prevent the waters of the Duddon being utilised for a similar purpose. The motion was adopted.

Edinburgh.—The estimates of the Town Council for the current year show an increase of £4,338 for electric lighting as compared with last year, but as the Council did not spend all the money last year which they estimated for the electric light, there is actually only an increase of £1,725. A meeting of a sub-committee of the Lord Provost's Committee of the Edinburgh Town Council has been held, at which a memorandum bearing on the subject of the proposed amalgamation of Edinburgh, Leith, and Portobello was submitted. It was mentioned that as the Corporation of Edinburgh are now engaged in introducing the electric light, under the amalgamation proposed, the system of electric lighting could be carried into the united burgh under the same system and from the same source as the Edinburgh light. The meeting of the Edinburgh and Leith Gas Commission was held on Monday, when the chairman, Councillor Anderson, compared the cost of gas and electric lighting. He asserted that the illuminating value to be got for 3s. 6d. would be respectively: incandescent electric light lamps, 1,540 candles; gas consumed in a 5ft. per hour jet, 5,000 candles; gas consumed in an incandescent burner, 18,440 candles. The renewals for both gas and electric incandescent lamps had to be taken into account, but for an equal amount of light the electric lighting in Edinburgh would cost more than thrice the cost of gas in ordinary burners, and 12 times as much as in incandescent burners. He thought it assured that the gas industry would not go to the wall just at once.

Liverpool.—The Warehouse Committee, at the last meeting of the Mersey Docks and Harbour Board, recommended the Board to establish a system of electric lighting at the Albert Dock warehouses at an estimated cost of £2,850. Mr. Robert Gladstone said the committee had for some time past been considering various methods whereby the warehouses at the Albert Dock might be made more efficient and more productive of revenue, and they had at last unanimously resolved that the electric light should be adopted in all the floors. They did not recommend it to be put into the cellars or vaults where gas appeared to be more suitable in many ways, but they were quite satisfied that the electric light all over the warehouses would be of very great advantage, not only in regard to any risk of fire that might be incurred at present, but also because it would enable work to be done at night and on dark days in winter much more thoroughly and satisfactorily than it was done now. They proposed also to have a number of loose cables of considerable length which could be carried into the holds of ships and illuminate them to such an extent that work could be done there at night without the smallest difficulty. The committee were hopeful that by exercising the utmost economy they would be able to do the work at a less sum than £2,850, but they asked the Board to give them power to spend that amount, because it might eventually be found necessary. The further consideration of the recommendation was, in accordance with the standing orders, postponed till next meeting.

Loan to Shoreditch Vestry.—The Finance Committee of the London County Council reported on Tuesday that they had considered an application from the Vestry of Shoreditch for sanction to the borrowing of £12,300, on the annuity system for 60 years, for the purchase of land for dust destructor and electric lighting station. The Vestry has power under the Public Health (London) Act, 1891, Amendment Act, 1893, and the Electric Lighting Orders Confirmation (No. 6) Act, 1892, to purchase land for the purposes mentioned, and to borrow the money required, and they have agreed to purchase a site in Coronet-street and Hoxton-square for the sum of £12,300. The site contains an area of about 25,266ft., the greater portion of which is freehold, a small portion being leasehold, for a term expiring at Lady Day, 1929, at a nominal rent of 1s. The price to be paid is about 11s. per foot, which the Council's valuer considers fair and reasonable As the full period could not be allowed for repayment of the loan as affecting the leasehold part of the property, the committee have thought it convenient to reduce the amount by £100, its estimated present value, and as the Vestry only asks for permission to borrow, they recommend that the seal of the Council be affixed to an order sanctioning the borrowing by the Vestry of Shoreditch of £12,200 towards defraying the cost of purchasing a site for a dust destructor and electric lighting station at a rate of interest not exceeding £3 10s. per cent. per annum, such sum being repaid by such equal half-yearly or annual payments of principal and interest combined as will repay the amount borrowed within a period of 55 years from the date of the loan. The recommendation was adopted.

The Leeds Tramways.—A motion was brought before the Leeds Town Council on Wednesday by Mr. Graham, who proposed that the Council should adopt the cable system of traction for the city tramways. The Mayor reminded Mr. Graham that the question was under the consideration of the Tramways Committee, and thought it would necessarily come before the Council on a recommendation of the committee. He did not know whether Mr. Graham might not consider it premature to bring forward the subject now. Mr. Graham said it was several months since the question was referred to the committee, and yet no recommendation had been made. Of all the methods of traction he considered the cable system the best. He certainly would not like to see the electric system now in use on the Roundhay-road section adopted all over the city. He was of opinion that it would be much better that a company, rather than the Corporation, should manage the tramways. Alderman Gaunt, in seconding the motion, said that if the committee could not make up its mind to bring some system before the Council, he would assist Mr. Graham in bringing the subject forward. Mr. Wilson thought the resolution was inopportune. Alderman Firth thought it was unfair while the committee were considering the matter to hurry the question in a way that might damage the interests of Leeds for the next 20 years. The Tramways Committee had not yet as a committee expressed any opinion as to the method they ought to recommend, and they should not be expected to bring forward a partial report. The committee would give its opinions on all the systems they had seen, and would recommend the one which they thought the best to adopt. He appealed to the Council to show its confidence in the committee until it brought forward its report. Mr. Graham was satisfied with having provoked a discussion, and with the consent of the Council withdrew his resolution.

Islington.—At a meeting of the Vestry a report was received from the Special Electric Lighting Committee stating, that with a view to preventing difficulties arising with the owners of the property in Eden-grove and Burnard-place, adjoining the site, and to remove the possibility of the Vestry being sued for infringements of the rights of such owners, and also in order to afford facilities for further extension of the works, the committee is of opinion that such property should be acquired by the Vestry, if it can be obtained at a reasonable cost, and has with this end in view directed negotiations to be opened up with various persons interested in such property; and recommending—(*a*) That, as it considers the offer of the freeholder and lessee of 3, Burnard-place (which is now let at £28 per annum, the tenant paying rates and taxes), to join and convey to the Vestry outright and to give vacant possession on completion for the sum of £450, and vendor's solicitor's costs, according to scale, a reasonable one, such offer be accepted subject to a good title being shown, and that the solicitor be instructed to complete the purchase. (*b*) That the offer of the Rev. Frederick Mann to convey to the Vestry his freehold interest in Nos. 5, 7, 9, 19, 21, and 23, Burnard-place (subject to the leases thereon), for the sum of £600 and vendor's solicitor's costs according to scale, be accepted subject to a good title being shown, and that the solicitor be instructed to complete the purchase. The report was agreed to. Mr. Lambert pointed out that on the site for the station there were two little houses, situate close to the place where the stack was to be erected. He thought it would be policy if the property were purchased. It would be useful in future years. Mr. D. W. Williams thought the committee should be given power to acquire the property. This was agreed to. The Vestry Clerk said he would ask the Vestry to pass a formal resolution asking the County Council for a loan of £51,000, the balance of £60,000, for the purpose of completing the electric lighting works. He believed the County Council would be willing to lend the money for 42 years. Mr. Lambert moved that application be made to the London County Council or some other body for a loan of £51,000 for 42 years, at a rate of interest not exceeding 3½ per cent., repayable on the annuity system. Mr. D. W. Williams seconded. Mr. Dryden thought the rate of interest was too high. He believed the County Council lent money to some authorities at 3⅛ per cent. The motion was agreed to.

Lighting of Woking.—The Local Board have opened tenders for lighting the Woking Station and Maybury Ward. They were as follows: Messrs. New and Mayne (electric light)—capital expenditure for 34 single and 13 two-light lamp columns, £400, or for 48 single and 13 double light columns, £513. 15s.; current, etc., to 60 incandescent lamps, each of 25 c.p., £252, or for 70 lamps, £310. 16s., capital to be repaid within five years, with interest at 5 per cent. per annum. The Woking District Gas Company (gas)—capital expenditure for 100 street lamps, £300; gas to same for 2,000 hours per annum, £265; agreement for three years and subject to six months' notice, interest on capital expenditure 5 per cent., 2½ per cent per annum discount to be allowed for depreciation. The clerk was instructed to write to Messrs. New and Mayne enquiring (1) whether they would be willing to make a proportional allowance if the Board did not require 2,000 hours' installation and charge a proportionate increase for any further lights that may be required; (2) whether, as they proposed to charge interest at the rate of 5 per cent. per annum for capital outlay, they would, as in the case of previous tender, be willing to make an allowance of 2½ per cent. per annum for depreciation if and when the Board take over the plant; (3) whether they would be content to extend the period of purchase from five to seven years; (4) within what period could they complete the installations? The clerk was also instructed to write to the gas company as to extending the period of purchase to seven years, and the period by which they could complete the installation. At a subsequent meeting of the Lighting Committee it was resolved that the tender of Messrs. New and Mayne be recommended to the Board for acceptance; that 48 25-c.p. lamps be provided, and 13 two 25-c.p. lamps be provided; capital cost £513. 15s., or cost price, after giving credit for all discount. Messrs. New and Mayne to be allowed 20 per cent. for establishment charges, etc. The committee recommended the latter offer for acceptance. Capital to be repaid at the end of seven years, less 2½ per cent. per annum for depreciation; interest at

Digitized by Google

5 per cent. per annum on capital expenditure to be paid by Board; cost of current for 2,000 hours per lamp with proportionate allowance £310. 16s ; minimum of 1,000 hours per annum per lamp The committee further recommended that the Board authorise this committee to settle the actual terms of contract, and arrange for the immediate carrying out of the work, and that the clerk be authorised to instruct counsel to settle contract and advise thereon as necessary. Mr. Harris moved at the last meeting of the Local Board that the report be adopted. Mr. Storey seconded the adoption of the report, which was carried.

PROVISIONAL PATENTS, 1894.

JULY 23.

14113. **Improvements in electric energy and power recording meters.** Alfred George Cooper, 43, George-lane, Lewisham, Kent.

14123. **Improved method of fixing electric bells and telephones.** William Paul Theermann and George Christopher Elliott, 11, Great Ducie-street, Manchester.

14156. **Improvements in or connected with electrical wagons.** Oliver William Ketchum, 4, South-street, Finsbury, London.

JULY 24.

14202. **Improvements in signalling by electric lamps.** Hugh Donald Fitzpatrick, 70, Wellington-street, Glasgow. (The Boughton Telephotos Company, United States.) (Complete specification.)

14246. **An improved system of electrical distribution by alternating currents.** Charles F. Scott, 28, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, sec. 103 February 26, 1894, being date of application in United States.) (Complete specification.)

JULY 25.

14290. **Improvements in electrical lampholders and similar electrical fittings.** Gustav Binswanger, 73, St. Stephen's-road, Upton Park, London. (Complete specification.)

14303. **An improved electricity motor meter.** Carl Raab, 6, Lord-street, Liverpool.

14312. **Improvements in automatic switch devices for electric currents.** James Thornhill Ashton, 323, High Holborn, London.

14320. **Improvements in dynamo-electric machines and electromotors.** John Augustine Kingdon, 54, Beresford-road, London.

14327. **Improvements in the manufacture of aluminium and aluminium alloys, and the electro-deposition of the same.** Alfred Francis Bilderbick Gomess, 9, Warwick-court, Gray's inn, London.

JULY 26.

14371. **Improvements in fire-alarm telegraphs.** George Richard Neilson and Alfred Charles Brown, Winchester House, Old Broad-street, London.

14394. **Improvements in induction coil apparatus for electro-medical and other purposes.** Henry James Dale, 115, Cannon-street, London.

JULY 27.

14445. **Improvements in or connected with electric railways and vehicles.** James Yates Johnson, 47, Lincoln's-inn-fields, London. (Malone Wheless, United States.) (Complete specification.)

14488. **Improvements in or connected with electric arc lamps.** James Jeffryes and John Lea, 166, Fleet-street, London.

JULY 28.

14492. **An improvement in the chamber or reflector for carrying the lamps used in photographing by the electric light.** Andrew George Adamson, 154, St. Vincent street, Glasgow.

14493. **Improvements in apparatus for the use of electric light for photographic purposes.** Andrew George Adamson, 154, St. Vincent street, Glasgow.

14509. **Improvements in electric current regulators.** Herbert Vivian Keeson, 40, Loudoun-road, St. John's Wood, London.

14511. **An improvement in electric stop-motion drawing frames.** Robert Hartley and James B. Cocks, 243, Entwistle-road, Rochdale.

14518. **Improvements in telephone switchboard apparatus.** Alfred Whalley, Ashville, Helsby, near Warrington.

14533. **Improvements in apparatus for transforming electric currents.** John Ambrose Fleming, University College, Gower-street, London.

14536. **Improvements in apparatus for heating and welding by electricity.** Charles Frederick Parkinson and Walter Gatwood, 6, Bank-street, Manchester.

14545. **Improvements in the construction of dynamo-electric machines and electromotors.** Thomas Parker, Limited, and Thomas Parker, 55, Chancery-lane, London.

14546. **Electric contact by weight.** Sally David, 18, Somerfield-road, Finsbury Park, London,

14551. **Improvements relating to the transmission of signals through submarine cables and other telegraph and telephone lines, and to apparatus therefor.** David Young, 11, Southampton-buildings, Chancery-lane, London. (John Mabry McMahan, United States.)

SPECIFICATIONS PUBLISHED.

NOTES.

Theatre-Lighting.—The Tyne Theatre, at Newcastle, is now electrically lighted.

Electric Lighting at Prague.—The local gas company propose to establish a central electric supply station.

Electric Lighting at Andelot.—The Electric Light Committee are enquiring into the question of the adoption of the electric light.

Electricity at Trogen.—Preparations are being made for the introduction of the electric light into Trogen, Appenzell, Switzerland.

Electric Lighting at Meissen.—Messrs. Otto and Schlosser have submitted to the Municipality a scheme for the electric lighting of the town.

Electric Lighting at Bayonne.—Messrs. Brillouin and Delgay will shortly commence operations in connection with the central electric light station.

Bleaching by Electricity.—It is announced from Greiffenberg that a local firm, Messrs. Keferstein, are now using electricity in their bleaching works.

Electric Lighthouse at Stralsund.—The Arkona lighthouse is to be lighted electrically. The Crampas-Sassnitz harbour is also to be similarly lighted.

Electric Traction at Zurich.—The Municipality are considering the question of the acquisition of the tramways and the introduction of electric traction thereon.

A Pacific Cable.—As will be seen from "Contracts" column, the Canadian Government intend to lay a cable across the Pacific between Canada and Australia.

Electric Traction at Mylau (Saxony).—The local electric tramway company have now got the whole line in operation from Zwickau railway station to Schedewitz.

Electric Traction at Liege.—The Municipality have approved of the Union Elektricitäts-Gesellschaft of Berlin establishing electric traction on the local tramways.

Electric Light at Neu-Lockstedt.—The streets here are to be lighted electrically, current being obtained from Alt-Lockstedt, which has been electrically lighted for some time.

Electric Traction at Besancon.—Mr. Faye has asked for a concession for a system of electric tramway lines at Besançon. He is already interested in those of Dijon.

Electric Traction at Munich.—The local authorities have approved of electric traction being adopted on the tramway between Fürbergraben and Isarthal railway station.

Berlin Electric Traction.—The Government have approved of the scheme for an electric railway in the Berlin suburbs between Lichterfelde, Lankwitz, and Steglitz.

Telegraph and Telephone Circuits.—Mr. W. Christiani deals in the *Elektrotechnische Zeitschrift* with the employment of common circuits for Morse and telephone working.

Telephony at Brum.—A correspondence of complaints is appearing in the Birmingham papers on the subject of the unsatisfactory service of the local telephone exchange.

Fire at Chicago.—Damage by fire to the extent of £120,000 is reported to have been done last week at the Chicago works of the Siemens and Halske Electrical Company.

Electric Traction at Pankow.—Good progress is being made in connection with the electric tramway between Pankow and Gesundbrunnen. It is to be on the overhead system.

Electric Lighting at Metzingen.—An electric plant is being erected by an Esslingen firm in the Loh mill for the lighting of some local inns. The parish church is also to be lighted.

Bristol Electric Tramway.—The specifications and drawings for the new electric tramway are in a forward state, and the work of construction will be commenced without loss of time.

Electric Boats for the Police.—The Christiania authorities have decided to adopt electric propulsion for the police boats, Messrs. Lehmann and Mann, of Berlin, supplying the accumulators.

Train Indicator.—An illustrated description is given in *L'Electricien* of August 4 of the Hoffmann apparatus for indicating in railway stations the time of departure of trains and their destination.

Lighting of Auer Lamps.—A method of lighting Auer gas lamps by electricity has been devised by M. Serrin. The gas is lighted by a spark produced by a Ruhmkorff coil energised from three or four cells.

Electric Lighting at Schiltigheim.—The Elsässische Elektricitätswerke, of Strassburg, are substituting electric lighting for gas lighting in the works of the Erste Elsässische Küferei Aktiengesellschaft.

Iron and Steel Institute.—At the Brussels meeting of this institute, to which reference was made in our last issue, a paper "On Electrical Power in Belgian Ironworks," by Mr. D. Selby-Bigge, will be presented.

Personal.—Mr. J. E. Edgcombe, the electrical engineer to the Kingston Corporation, having got married, the members of the Lighting and Drainage Committees of the Town Council have presented him with a silver salver.

Electric Traction at Baden (Austria).—An electric tramway has been opened between Baden, near Vienna, and Helenenthal. By the end of the month an extension from Helenenthal to Vöslau will be completed.

India-Ceylon Telegraph Line.—When the new telegraph cable from Ceylon to India *vid* Talamannar is made in September next, Ceylon will receive the duplex system. At present Madras has the duplex and quadruplex systems.

Electric Lighting at Mylau (Saxony).—In response to circulars sent out with respect to the probable demand for current for electric lighting purposes, applications have been received for over 1,400 lamps, apart from street-lighting.

Schonlinde (Austria).—The local authorities have entrusted Messrs. Kremenezky, Mayer, and Co., of Vienna, with the contract for the erection of a central station. There will be two single-cylinder steam-engines running at 130 revolutions per minute.

Central Station at Linden.—Mr. Ernst Bremeyer, a local indiarubber manufacturer, proposes to erect a central electricity station at his works for the supply of current for lighting and power purposes. A considerable number of applications has already been received.

Electrolytic Works at Osternienburg.—The German Solvay Works, of Bernburg, have proposed to erect an electrolytic works at Osternienburg for the manufacture of chemicals, but opposition is coming from local landowners on the grounds that the gases will be injurious to their interests.

Digitized by Google

Windmills and Electricity.—A unique plant is to be established at Bremen. The owner of the Ansgariithor windmill intends to make use of electricity, not by making his windmill drive a dynamo, but by introducing an electromotor, connected with the town electric mains, for driving his machinery when a calm prevails.

Electricity at Antwerp.—The Deutsche Elektricitäts Werke of Aix-la-Chapelle have constructed 60-h.p. turbine dynamos for the Antwerp central station. Though, as a rule, dynamos are considerably smaller than their motors, in this instance the reverse is the case, as a very high pressure is used for driving the turbines.

Electric Lighting at Augsburg.—A long time back the local gas company informed the Municipality that they were prepared to introduce the electric light, and some weeks ago prepared a plan for lighting the town electrically. This was not considered satisfactory, and a new plan has been drawn up. It is believed the work will be commenced next year.

Electric Transmission in Ain.—The water power of the River Valserine has already been utilised for driving the dynamos of the oldest electric light station in France, that of Bellegarde-sur-Valserine, Ain, but only 120 h.p. is employed there. Mr. J. Guillemet has now drawn up a project whereby about 7,500 h.p. would be made available.

Gotha is Not Up to Date.—A grant of £185 was wanted for the electric lighting of the School of Building. This cost was only one-fifth higher than for lighting by means of Auer incandescent gas lamps, but the Gotha Diet has declined to grant the money on the ground that there is so little experience available with respect to the electric light. The Duke of Edinburgh would do well to educate his new subjects.

Electric Traction at Loipzig.—The Municipality have given a concession to the Allgemeine Elektricitäts-Gesellschaft and Mr. R. Lehfeldt, of Leipzig, for the construction and working of an electric tramway. The new lines will traverse the whole of the inner part of the town, which has hitherto not been served by any tramway. The system of lines for which the concession has been granted amounts to over 21 miles.

Electric Traction at Strassburg.—Preparations are being made by the tramway company for using electric traction on the lines in the central parts of the town. Arrangements are being made with the Allgemeine Elektricitäts-Gesellschaft of Berlin for the supply of motor cars. These will be tried until it has been demonstrated that electric traction is satisfactory. When there is heavy traffic it is intended to use a trailer behind the motor car.

Central Station at Gegenbach (Baden).—The local authorities have given a 25 years' concession to the Offenburg Colliery Company for a central station for lighting the town. Messrs. O. L. Kummer and Co., of Dresden, will carry out the work. The supply station, of a capacity of 1,000 lamps, will be erected at the Berghaupten Colliery of the company, which is about 2½ miles distant from the lighting district. The transmission will take place by means of an alternating current of 3,000 volts.

Electrical Stern Attachment for Launches.—With reference to the note on this subject in our last issue, Mr. E. A. McLachlan writes as follows: "Kindly correct the following mistakes. The headnote reads in your paper 'Electrical *Steam* Attachment for Launches.' This should be 'Electrical *Stern* Attachment.' The other mistake states that the electrical equipment can be supplied to any boat at about one-half the cost of an ordinary 'electric *lamp*.' This should be 'electric *launch*.'"

Strange Story from Blackpool.—Complaint was made at the Blackpool Town Council meeting on Tuesday that serious attempts had been made to interfere with the electric light supply and the running of the electric tramway during the busy season. Scientific measures had been taken to run the tramway current to earth, and to otherwise hamper the staff, the interference being of so damaging a nature that a special watch would have to be maintained.

Strassburg.—The question of lighting the town electrically has been under consideration since 1889, and at last a decision has been come to. The Municipality have determined to allow the Allgemeine Elektricitäts-Gesellschaft of Berlin to erect and carry on a central station. It will be built on plans by Mr. Oscar von Miller, and alternating current will be employed. Steam power will be used at first, but probably when extensions are made the power of the Rhine will be utilised. The concession is for 40 years.

Ammeters and Voltmeters.—A price list of the ammeters and voltmeters constructed according to MM. Desruelles and Chauvin's patent has reached us from the Boudreaux Dynamo Brush Company, who are the English agents for these instruments, which have gained a good reputation in France for their great accuracy and high-class workmanship. In addition to these the company furnish galvanometers, resistance-boxes, portable testing sets, and Desruelles standard cells (giving one volt exact), of the same manufacturers.

Owens College, Manchester.—A special course has been arranged on the technical applications of electricity. A dynamo-house has recently been built in connection with the physical laboratory, containing a 7-h.p. Otto gas-engine, with two direct and two alternate current dynamos, specially constructed for purposes of instruction, etc. In the laboratory full instruction is given in electric and magnetic measurements, testing of dynamos, etc. The session begins on October 2. Prospectus may be obtained of Mr. H. W. Holder, M.A., registrar.

Portable Electric Pumping Plant.—The *Bulletin International de l'Electricité* refers to a portable electric pump devised by Messrs. Carl and Co., of Worms, for use in breweries and cellars. The motor and pump are arranged on a kind of trolley, the former driving the latter by means of worm gearing. The motor is put into the circuit of the existing electric light installation by means of a flexible cable, which is connected to any one of the various wall plugs in the building. The motor is made in sizes ranging from ⅓ h.p. to ¾ h.p., and the plant is said to be more economical than pumping by hand.

University College, Liverpool.—The engineering department for session 1894-95 commences on October 2. Complete courses of instruction have been arranged in civil engineering, mechanical engineering, and electrical engineering. These courses enable students to qualify for university degrees and for the college certificates in engineering. They comprise, in addition to special engineering lectures and laboratory work, instruction in mathematics, physics, electrotechnics, and chemistry. The engineering laboratories, and also the electrotechnical laboratories, are completely equipped with modern appliances. The college prospectus, and also the special engineering prospectus, can be obtained on application to the registrar.

Electric Lamps in Railway Carriages.—Mr. Boiston's electric reading lamps, according to *Indian Engineering*, will be given an extensive trial on the system of railways worked by the Bombay, Baroda, and Central India Railway Company. Some time back an experimental arrangement was made with Mr. Boiston for the

Digitized by Google

erection of automatic machines at stations on the company's system. The company have since agreed to Mr. Boiston's proposal to introduce an electric reading lamp in carriages on passenger trains, and to this appliance being included in the concession granted to Mr. Boiston in respect of the experimental introduction of automatic machines. The fitting of the lamps will be done under the supervision of the carriage department of the railway.

Central Station at Frankfort-on-the-Maine.—This station was in the first place calculated for a capacity of 17,500 lamps simultaneously alight. For the four steam-engines projected, only three engines, with their corresponding boilers, have been authorised. The number of applications amount to 29,000 lamps, or their equivalent in motors, or equal to about 17,100 lamps simultaneously alight. In addition, there will be the lighting of the harbour, the municipal hospital, and of some public streets and offices. An agreement has been made with Messrs. Brown, Boveri, and Co. to extend the plant. This extension will include a steam dynamo and six boilers. Applications are constantly being received, some of which come from outside the district of the network of conductors at present planned.

The Snowdon Electric Railway.—The route surveyed for the electric railway from Llanberis to the summit of Snowdon covers a distance of over six miles. It starts from the Ty Clwb, near the Victoria Hotel, goes up to Ceunant Mawr, past the Llanberis waterfall, then turns on the left to the top of Derlwyn, and passes along the tops of the mountains on the west side of the Pass of Llanberis, as far as Clogwyn Coch, where the line will turn to the right and proceed as far as the Crosses; then, after running along the mountain side opposite the Snowdon Ranger Path, it will turn to the left and proceed direct to the top of Snowdon. It runs, in fact, near the Llanberis ascent. A limited company, it is reported, is about to be formed to carry out the scheme, and already half the required capital has been secured.

Notes from Italy.—The Town Council of Verona has lost the action brought against it by the local gas company for having granted a concession to an electric light company—the gas company having by its contract a lighting monopoly. A French company which had obtained powers for the electric lighting of Venice, has now declined to undertake the work. The company operating the station in Reggio Emilia has been in difficulties, but as a compromise has now been effected, the supply of light will be continued. The Edison Company of Milan has a concession for a line of electric tramway in the town, and negotiations were recently entered into with the local omnibus company, with a view to amalgamating the two undertakings. The latter has, however, declined to agree to the fusion.

Electric Lighting in Madras.—In the Madras Presidency two electric light installations have been recently carried out by Messrs. Oakes and Co., of Madras, one at the United Service Club, Bangalore, being an installation of 100 16-c.p. incandescent lamps run off a 105 volt circuit. A correspondent of the *Indian Engineer* states that the dynamo is of the Crompton type. In connection with this installation, or rather a part of it, is a set of accumulators, the battery consisting of 53 seven-plate cells of the Crompton-Howell type. The dynamo is driven by a Marshall 6-h.p. single-cylinder high-pressure stationary engine fitted with Hartnell's automatic expansion gear, the boiler being of the loco. type. The second installation put in by the company is at their own premises on the Mount-road, this being a somewhat smaller installation, comprising only 60 16-c p. incandescent lamps. The dynamo is driven by a 3-h.p. horizontal engine by Messrs. Robey and Co., supplied by steam from a 6-h.p. loco.-type boiler. Both installations were carried out by Mr. R. D. Frier, manager and engineer of the company's foundry.

Life of Incandescent Lamps.—One can hardly attach much—if, indeed, any—value to tabular statements of the life of different types of incandescent lamps, their consumption of current, and cost price per candle per hour when the lamps are designated purely by alphabetical letters, without any indication being made of the type or make of the lamps. This policy is being followed by *L'Industrie Electrique*, which some weeks ago dealt with this subject at some length; and an esteemed English contemporary, without taking into consideration the uselessness of such a compilation, subsequently reproduced the article. *L'Industrie Electrique* has now followed up its former article by a second, which is given in its issue of July 25. In this case, too, the various types of lamps are merely designated by letters, and consequently the article is of little, if any, practical value. We would suggest that in the future the names should be specifically mentioned.

Communication Between Lightships and the Shore.—In the House of Commons a few days ago, Mr. Bryce, in answer to Major Jones, stated that the committee to which the hon. member would appear to refer reported and closed its sittings in 1889. The whole subject of electrical communication between lightships and the shore was now being dealt with by the Royal Commission on Electrical Communication with Lighthouses and Light-vessels. He understood that a number of inventions, including various modes of applying swivels, for establishing electrical communication between lightships and the mainland had been considered by the Royal Commission, and he would refer the hon. member to the paragraph at the top of page 8 of their second report, dated March last, in which the Commissioners stated that, in their opinion, none of the inventions which they had considered were preferable to the system known as the "Sunk" system, which had now been applied to the Goodwin and Kentish Knock light-vessels. He had no doubt that the Royal Commission would consider, and, if necessary, test, any inventions brought before them which appeared to them to be superior to the "Sunk" system.

Train-Lighting.—An article on the electric lighting of the Danish State railway trains appears in the *Elektrotechnische Zeitschrift* of the 2nd August from the pen of Mr. J. B. Brunn, inspector of machinery at Copenhagen. Before the question of improving the illumination of the carriages was decided upon, it was resolved to make preliminary experiments in a few coaches, and for this purpose accumulators furnished by the Electrical Power Storage Company, of London, were adopted. The results were successful, and in 1892 an extension of the system was ordered to be carried out on all the express trains in Zealand. In this case the batteries used are of the Hagen type, each battery comprising 33 cells with three in reserve, and two batteries are carried on each train. The first-class compartments are lighted by two 8-c.p. lamps, whilst the second and third class coaches are equipped with lamps of 5 c.p. The batteries are charged at the railway stations in Copenhagen and Helsingor. The author concludes that although the experiments have been conducted for over two years, they have not been continued sufficiently long to allow of an impartial comparison of the cost of oil-gas illumination and of electric lighting of trains.

Electric Cranes for Bridge Building.—A large arched bridge is now being built by the Gutehoffnungshutte, of Oberhausen, over the Baltic Canal near Levensau for foot passengers and for railway traffic, and in the course of

Digitized by Google

construction electricity is taking an important position for motive power purposes. This installation has been carried out by Mr. Gustav Conz, of Hamburg. The generating plant comprises two steam-engines coupled direct to compound dynamos, which are arranged to work in parallel, and which supply current to motors operating several electric cranes. Of course, in a case of this character the operation of cranes is very irregular. It is possible, as is pointed out by Mr. Paul Rohde in the *Elektrotechnische Zeitschrift*, that all the electric motors may at times be suddenly cut out of circuit. To meet this emergency, an automatic arrangement has been adopted at Levensau. By this means, when the outer circuit is opened, a shunt resistance is inserted, which prevents the paralleled dynamos from working against each other. This arrangement ensures the proper operation of the plant. The dynamos and motors are of the four-pole type, and the steam engines are compound, giving 25 h.p. at 400 revolutions, and provided with Tangye regulators.

Prizes Proposed to be Awarded.—The French Société d'Encouragement pour l'Industrie Nationale has issued a list of the prizes to be awarded in 1895-96. Among these may be mentioned the Henri Giffard award, to which reference was made in a previous issue, and the Melsens prize. The latter, which is offered for an application of physics or chemistry to electricity or to hygiene, is of the value of £200, and will be awarded in 1896. Awards of £80 each are to be made for a motor weighing less than 1cwt. per horse-power, and for a small motor for a domestic workshop. A similar offer is made for the commercial production of ozone and its applications. In the section "Arts Economiques," the following prizes for next year are proposed: The sum of £80 for an apparatus or industrial method for measuring or estimating the insulation of various parts of an electrical installation in operation; £120 for the presentation of a material capable of replacing indiarubber in at least one of its principal applications, or for works having contributed towards developing the production or improving the working up of this material; and £80 for an incandescent electric lamp having an intensity of a decimal candle and working with $\frac{1}{20}$ ampere at 100 volts. Models, descriptive papers or notes, and samples are to be addressed to the Secrétaire de la Société d'Encouragement pour l'Industrie Nationale, 44, Rue de Rennes, Paris, not later than December 31, 1894.

The Douglas Electric Tramway.—It will be remembered that this tramway, to which we have from time to time referred, was completed and opened as far as Groudle Glen, half the full distance, last summer. The traffic, especially since the whole of the line has been opened, is very large, as it affords a pleasant excursion for the summer visitors to the island. The line is seven miles in length, being double all the distance. It is a surface line, following for the most part the contours of the hilly country through which it passes, but at the Douglas end there is a cutting along the face of the cliff, this portion of the road being protected seaward by a massive cement concreted wall. At other portions of the line there are some long gradients, the steepest being 1 in 24. The line is made of the ordinary steel rails, laid on transverse sleepers. The speed is, by Act of Tynwald (the Manx Parliament), limited to eight miles an hour. The cost of the line, including the plant, rolling-stock, and electrical machinery, is about £9,000 a mile. Each train consists of one motor car and one trailing car, the two vehicles being together capable of seating 82 persons. The current is produced at two stations—one at Douglas and the other at the Laxey terminus. At the former end there are three steam-engines and three boilers, each engine driving a 50-kilowatt dynamo of the Manchester type. There is also a large accumulator station about halfway along the line. The current produced by the dynamos is conveyed by copper conductors supported by steel poles erected along the line. Two uprights fixed on each motor car carry a horizontal copper collecting bar, which conveys the current from the conductors to two 30-h.p. motors fixed underneath each car. These motors are geared to the axle of the driving wheels. The return is through the rails, which are connected by a copper strip at each joint. The whole of the electrical plant and machinery has been designed by Dr. E. Hopkinson, the contractors for the work being Messrs. Mather and Platt, of the Salford Iron-works, and the engineer by whom the tram line was constructed is Mr. Frederick Saunderson, of Douglas.

Lighting of Drainage Works.—Before the Manchester meeting of the Institution of Mechanical Engineers, last week, Mr. Wm. Thomas Olive gave a description of the Manchester main drainage works. The paper concluded with the following statement concerning the electrical plant at those works: The installation includes a vertical engine with 13in. cylinder and 16in. stroke to run at 130 revolutions per minute with a pressure of 80lb. per square inch, the steam being supplied from the general service boilers. Also a set of 56 storage batteries capable of running with lamps of 16 c.p. a maximum of 420 lamp hours. The dynamo is driven at a speed of 700 revolutions by a 10in. flexible centre belt direct from the engine fly-wheel, which is 5½ft. diameter and 11½in. wide on the face; it is of the inverted-magnet type, compound wound, and has a capacity for working a 220-ampere load at 100 volts when on the lamp circuits. When charging accumulators a plug switch is inserted in the series portion of the compound winding, which cuts that part out of action. For charging the accumulators in series the speed of the dynamo would require to be nearly 1,000 revolutions per minute, with a corresponding increase in speed of engine. As this, however, would materially increase the wear and tear, the batteries by means of suitable switches are arranged in two sets of 28 each when charging. By this means the speed is reduced to about 600 revolutions per minute, thereby effecting also a saving of steam. Although storage batteries usefully yield only about 70 per cent. of the energy given to them by the dynamo, they are extremely economical and handy. If a small number of lamps only are required, it would be wasteful to run the engines; besides which time would be occupied in oiling and heating up, and there would be loss by condensation. From the accumulators the lamps can be started or stopped instantly without any further attention. As the insulated cables spread for hundreds of yards in every direction about the premises, the stored energy could be applied on an emergency to portable machines for pumping, drilling, hauling, etc. The number of lamps at present in use is 134, as follows: 14 arcs of 1,200 c.p. for outside use, 12 arcs of 500 c.p. for inside use, 88 incandescent lamps of 16 c.p. for inside use, eight incandescent lamps of 50 c.p. on the approach road, and 12 incandescent lamps of 32 c.p. in the subway. These are divided on the switch-board into six main circuits, but there are also local switches for every one or two lamps, except on the approach road, where all the lamps are controlled by one switch. An illustration occurs here of the economy of electric lighting as compared with gas. To light and extinguish gas would occupy a man at least an hour every day, whilst the engine-man can turn the electric lamps on and off in an instant without leaving his post. The electric lamps also require less cleaning, as there is no smoke or soot, and the insides of lanterns are sealed from atmospheric dust.

FACTS AND FIGURES CONCERNING SOME CONTINENTAL ELECTRIC TRAMWAYS.

The Union Internationale Permanente de Tramways is an organisation which was formed in Belgium, but has spread its influence and connection over most of the continental countries to such good purpose that its annual meetings are now attended by nearly all the leading tramway engineers and officials of Germany, Belgium, France, Austria, and Italy. In this respect it takes a much higher position than our own Tramways Institute, and the information which it compiles and circulates has a value to our readers which they will appreciate on perusal. Particulars of construction and returns as to working cost, capital outlay, etc., have been obtained from a number of tramway companies whose officials are members of the union, and whose lines are operated by electric energy, and we propose to abstract these details in such form as may prove most useful to our readers.

The first line or system of lines to notice is that of **Aix-la-Chapelle**, where overhead conductors are employed with underground feeders. The trolley wire is of silicious bronze 8mm. diameter (equal nearly to No. 0 S.W.G.), supported in the usual way from poles with horizontal arms. Each car is provided with two motors, having a total capacity of 30 h.p.; there are some considerable grades on the lines which require the operation of both motors at once, but usually one is sufficient for working the car so that the second one in such a case acts as a reserve. The necessary current is derived from the municipal electric lighting station, being generated by two special sets of engines and dynamos having an output of 200 h.p. each at a working pressure of 600 volts. Under ordinary circumstances one set is enough for the daily load, the other being then in reserve, but both are worked for heavy service on *fêtes* and holidays, and should more current still be required a continuous-current transformer is put into action, so that the electric lighting machines at the central station may be drawn upon.

The total length of line worked electrically is 22 kilometres (or, say, 13·6 miles), of which two kilometres (1¼ miles) are constructed as double track. Of the entire system—

1,300	metres, or	6 %	are on the level.
15,400	„	70 %	have grades varying up to 2·5%.
2,800	„	12·5%	„ „ from 2·5 to 3·3%
2,499	„	11 %	„ „ „ 3·3 to 5%.
100	„	·5%	„ „ up to 9%.

Thirty-four motor cars are in service; they each accommodate 14 passengers seated and 12 standing on the platforms, therein resembling the horse cars previously used, but now turned into trail cars. The tramway company considers that double-decked cars—*i.e.*, those with seats on the roof—would offer many difficulties and inconveniences, more especially in regard to the trolley pole. Its officials evidently have not been to visit the South Staffordshire tramway, or they would know that there is not the least trouble in working double-decked cars on the overhead conductor system. At Aix, however, it is considered that the ordinary type of car will serve every purpose, especially as the introduction of electric working has increased by 25 per cent. the number of journeys accomplished daily by the cars.

So far as it can be stated with a fair degree of accuracy, the capital outlay upon these lines has been as follows:

	Marks.	
Overhead conductor system	210,000	£10,500
Motor cars (34)	374,000	18,700
Depôt and workshop	26,000	1,300
Permanent way—altering and making equal to new	200,000	10,000
Miscellaneous—sidings, etc.	90,000	4,500
	900,000	45,000
Deduct proceeds of sales—horses and cars	100,000	5,000
Total	800,000	£40,000

The speed of the cars is maintained at 10 kilometres (6·2 miles) per hour within the town limits, and 15 kilometres (9·3 miles) outside in the suburbs.

The lines at **Hamburg** are also operated on the overhead conductor system; their length amounts to a total of 22·761 kilometres, or about 14 miles. The sharpest curve has a radius of 20 metres, or about 62ft., nearly equal to one chain; the steepest grade is one of 5 per cent. about 300 yards long. The track is double throughout except on two short sections, measuring in all about 600 yards. Current for working the lines is provided by the Hamburg Electricity Works, and is conveyed to different points of the system by means of underground cables. In the central station there are at present two transformers, each giving 150 amperes at 500 volts, and a dynamo having an output of 200 amperes at the same voltage. The former are fed from the lighting circuits at a pressure of 250 volts. Other transformers are in process of erection. The overhead conductor or trolley wire is maintained at a height of 17ft. to 20ft. above the street level, and runs centrally over the track. The method of suspension varies according to local conditions. In some places poles with long arms or side brackets are fixed along the roadside or edge of the footpath, whilst elsewhere the usual type of steel suspension wires are used, strung across the streets from brackets fastened to the buildings. Switches at short intervals allow the current to be cut off from any part of the line at will. The trolley wire is of hard-drawn copper, 8·25mm. in diameter (equal to No. 0 S.W.G.). The poles from which it is supported are of ornamental design, and built of steel tubes. In order to avoid contact with broken telephone wires, the ends of which might conceivably fall upon the trolley wires, thin wooden protecting laths are carried by the latter. Each motor car has one 15-h.p. motor with single-reduction gear; the motor is hung in the usual manner, so as to rest the greater portion of its weight upon the car frame by means of a spring, the remainder being carried by the axle. Resistances are used for speed regulation; the car is driven in either direction from either end, and may be pulled up suddenly when required by reversing the current. Five 16-c.p. lamps are fitted to each car—three in the body and the others in the end lights.

(To be continued.)

THE BRITISH ASSOCIATION.

The sixty-fourth session of the British Association commenced at Oxford on Wednesday last. The presidential address by the Most Hon. the Marquis of Salisbury, and the addresses to Sections A and G by Prof. A. W. Rücker and Prof. A. W. B. Kennedy, respectively presidents of the sections referred to, all deal with matters closely allied to electrical science, and we therefore reprint them as follows:

Presidential Address

BY THE MOST HON. THE MARQUIS OF SALISBURY, K.G., D.C.L., F.R.S., Chancellor of the University of Oxford.

My functions are of a more complicated character than usually is assigned to the occupants of this chair. As chancellor of the university it is my duty to tender to the British Association a hearty welcome, which it is my duty as president of the association to accept. As president of the association I convey, most unworthily, the voice of English science, as many worthy and illustrious presidents have done before me; but in representing the university I represent far more fittingly the learners who are longing to hear the lessons which the first teachers of English science have come as visitors to teach. I am bound to express on behalf of the university our sense of the good feeling towards that body which is the motive of this unusual arrangement; but, as far as I am personally concerned, it is attended with some embarrassing results. In presence of the high priests of science I am only a layman, and all the skill of all the chemists the association contains will not transmute a layman into any more precious kind of metal. Yet it is my hard destiny to have to address on scientific matters probably the most competent scientific audience in the world. If a country gentleman, who was also a colonel of volunteers, were by any mental aberration on the part of the commander-in-chief to be appointed to review an army corps at Aldershot, all military men would

Digitized by Google

doubtless feel a deep compassion for his inevitable fate. I bespeak some spark of that divine emotion when I am attempting to discharge under similar conditions a scarceless less hopeless duty. At least, however, I have the consolation of feeling that I am free from some of the anxieties which have fallen to those who have preceded me as presidents in this city. The relations of the association and the university are those of entire sympathy and goodwill, as becomes common workers in the sacred cause of diffusing enlightenment and knowledge. But we must admit that it was not also so. A curious record of a very different state of feeling came to light last year in the interesting biography of Dr. Pusey, which is the posthumous work of Canon Liddon. In it is related the first visit of the association to Oxford in 1832. Mr. Keble, at that time a leader of university thought, writes indignantly to his friend to complain that the honorary degree of D.C.L. had been bestowed upon some of the most distinguished members of the association: "The Oxford doctors," he says, "have truckled sadly to the spirit of the times in receiving the hodge-podge of philosophers as they did." It is amusing, at this distance of time, to note the names of the hodge-podge of philosophers whose academical distinctions so sorely vexed Mr. Keble's gentle spirit. They were Brown, Brewster, Faraday, and Dalton. When we recollect the lovable and serene character of Keble's nature, and that he was at that particular date probably the man in the university who had the greatest power over other men's minds, we can measure the distance we have traversed since that time; and the rapidity with which the converging paths of these two intellectual luminaries—the university and the association—have approximated to each other. This sally of Mr. Keble's was no passing or accidental caprice. It represented a deep-seated sentiment in this place of learning which had its origin in historic causes, and which has only died out in our time. One potent cause of it was that both bodies were teachers of science, but did not then in any degree attach the same meaning to that word. Science with the university for many generations bore a signification different from that which belongs to it in this assembly. It represented the knowledge which alone in the Middle Ages was thought worthy of the name of science. It was the knowledge gained not by external observation, but by mere reflection. The student's microscope was turned inward upon the recesses of his own brain, and when the supply of facts and realities failed, as it very speedily did, the scientific imagination was not wanting to furnish to successive generations an interminable series of conflicting speculations. *That* science—science in our academical sense—had its day of rapid growth, of boundless aspiration, of enthusiastic votaries. It fascinated the rising intellect of the time, and it is said—people were not particular about figures in those days—that its attractions were at one time potent enough to gather round the university 30,000 students, who for the sake of learning its teaching were willing to endure a life of the severest hardship. Such a state of feeling is now an archæological curiosity. The revolt against Aristotle is now some three centuries old; but the mental sciences which were supposed to rest upon his writings have retained some of their ascendancy even till this day, and have only slowly and jealously admitted the rivalry of the growing sciences of observation. The subject is interesting to us, as this undecided state of feeling coloured the experiences of this association at its last Oxford visit, nearly a generation later, in 1860. The warmth of the encounters which then took place have left a vivid impression on the minds of those who are old enough to have witnessed them. That much energy was on that occasion converted into heat may, I think, be inferred from the mutual distance which the two bodies have since maintained. Whereas the visit of 1832 was succeeded by another visit in 15 years, and the visit of 1847 was succeeded by another visit in 13 years, the year 1860 was followed by a long and dreary interval of separation, which has only now, after four-and-thirty years, been terminated. It has required the lapse of a generation to draw the curtain of oblivion over those animated scenes. It was popularly supposed that deep divergences upon questions of religion were the motive force of those high controversies. To some extent that impression was correct. But men do not always discern the motives which are really urging them, and I suspect that in many cases religious apprehensions only marked the resentment of the older learning at the appearance and claims of its younger rival. In any case there is something worthy of note, and something that conveys encouragement in the difference of the feeling which prevails now and the feeling that was indicated then. Few men are now influenced by the strange idea that questions of religious belief depend on the issues of physical research. Few men, whatever their creed, would now seek their geology in the books of their religion, or, on the other hand, would fancy that the laboratory or the microscope could help them to penetrate the mysteries which hang over the nature and the destiny of the soul of man. And the old learning no longer contests the share in education which is claimed by the new, or is blind to the supreme influence which natural knowledge is exercising in moulding the human mind.

A study of the addresses of my learned predecessors in this office shows me that the main duty which it falls to a president to perform in his introductory address, is to remind you of the salient points in the annals of science since last the association visited the town in which he is speaking. Most of them have been able to lay before you in all its interesting detail the history of the particular science of which each one of them was the eminent representative. If I were to make any such attempt I should only be telling you with very inadequate knowledge a story which is from time to time told you, as well as it can be told, by men who are competent to deal with it. It will be more suitable to my capacity if I devote the few observations I have to make to a survey not of our science but of our ignorance. We live in a small bright oasis of knowledge surrounded on all sides by a vast unexplored region of impenetrable mystery. From age to age the strenuous labour of successive generations wins a small strip from the desert, and pushes forward the boundary of knowledge. Of such triumphs we are justly proud. It is a less attractive task—but yet it has its fascination as well as its uses—to turn our eyes to the undiscovered country which still remains to be won, to some of the stupendous problems of natural study which still defy our investigation. Instead, therefore, of recounting to you what has been done, or trying to forecast the discoveries of the future, I would rather draw your attention to the condition in which we stand towards three or four of the most important physical questions which it has been the effort of the last century to solve.

Of the scientific enigmas which still, at the end of the nineteenth century, defy solution, the nature and origin of what are called the elements is the most notable. It is not, perhaps, easy to give a precise logical reason for the feeling that the existence of our 65 elements is a strange anomaly and conceals some much simpler state of facts. But the conviction is irresistible. We cannot conceive, on any possible doctrine of cosmogony, how these 65 elements came into existence. A third of them form the substance of this planet. Another third are useful, but somewhat rare. The remaining third are curiosities scattered haphazard, but very scantily, over the globe, with no other apparent function but to provide occupation for the collector and the chemist. Some of them are so like each other that only a chemist can tell them apart; others differ immeasurably from each other in every conceivable particular. In cohesion, in weight, in conductivity, in melting point, in chemical proclivities they vary in every degree. They seem to have as much relation to each other as the pebbles on a sea beach, or the contents of an ancient lumber-room. Whether you believe that creation was the work of design or of inconscient law, it is equally difficult to imagine how this random collection of dissimilar materials came together. Many have been the attempts to solve this enigma; but up till now they have left it more impenetrable than before. A conviction that here was something to discover lay beneath the persistent belief in the possibility of the transmutation of other metals into gold, which brought the alchemy of the Middle Ages into being. When the immortal discovery of Dalton established that the atoms of each of these elements have a special weight of their own, and that consequently they combine in fixed ponderable proportions from which they never depart, it renewed the hope that some common origin of the elements was in sight. The theory was advanced that all these weights were multiples of the weight of hydrogen—in other words, that each elementary atom was only a greater or a smaller number of hydrogen atoms compacted by some strange machinery into one. The most elaborate analyses, conducted by chemists of the highest eminence—conspicuously by the illustrious Stas—were directed to the question whether there was any trace in fact of the theoretic idea that the atoms of each element consist of so many atoms or even of so many half atoms of hydrogen. But the reply of the laboratories has always been clear and certain—that there is not in the facts the faintest foundation for such a theory.

Then came the discovery of the spectral analysis, and men thought that with an instrument of such inconceivable delicacy we should at last find out something as to the nature of the atom. The result has been wholly disappointing. Spectral analysis in the hands of Dr. Huggins and Mr. Lockyer and others has taught us things of which the world little expected to be told. We have been enabled to measure the speed with which clouds of blazing hydrogen course across the surface of the sun: we have learnt the pace—the fabulous pace—at which the most familiar stars have been for ages approaching to or receding from our planet, without apparently affecting the proportions of the patterns which, as far as historical record goes back, they have always delineated on the evening sky. We have received some information about the elementary atoms themselves. We have learnt that each sort of atom when heated strikes upon the ether a vibration, or set of vibrations, whose rate is all its own, and that no one atom or combination of atoms in producing its own spectrum encroaches even to the extent of a single line upon the spectrum that is peculiar to its neighbour. We have learnt that the elements which exist in the stars, and specially in the sun, are mainly those with which we are familar upon earth. There are a few lines in excess to

Digitized by Google

which we can give no terrestrial name, and there are some still more puzzling gaps in our list. It is a great aggravation of the mystery which besets the question of the elements, that among the lines which are absent from the spectrum of the sun, those of nitrogen and oxygen stand first. Oxygen constitutes the largest portion of the solid and liquid substance of our planet, so far as we know it ; and nitrogen is very far the predominant constituent of our atmosphere. If the earth is a detached bit whirled off the mass of the sun, as cosmogonists love to tell us, how comes it that in leaving the sun we cleaned him out so completely of his nitrogen and oxygen that not a trace of these gases remains behind to be discovered even by the sensitive vision of the spectroscope ?

All these things the discovery of spectrum analysis has added to our knowledge ; but it has left us as ignorant as ever as to the nature of the capricious differences which separate the atoms from each other, or the cause to which those differences are due.

In the last few years the same enigma has been approached from another point of view by Prof. Mendeléeff. The periodic law which he has discovered reflects on him all the honour that can be earned by ingenious, laborious, and successful research. He has shown that this perplexing list of elements can be divided into families of about seven, speaking very roughly : that those families all resemble each other in this, that as to weight, volume, heat, and laws of combination, the members of each family are ranked among themselves in obedience to the same rule. Each family differs from the others ; but each internally is constructed upon the same plan. It was a strange discovery—strangest of all in its manifest defects. For in the plan of his families there were blanks left ; places not filled up because the properly constituted elements required according to his theory had not been found to fill them. For the moment their absence seemed a weakness in the professor's idea, and gave an arbitrary aspect to his scheme. But the weakness was turned into strength when, to the astonishment of the scientific world, three of the elements which were missing made their appearance in answer to his call. He had described beforehand the qualities they ought to have ; and gallium, germanium, and scandium, when they were discovered shortly after the publication of his theory, were found to be duly clothed with the qualities he required in each. This remarkable confirmation has left Mendeléeff's periodic law in an unassailable position. But it has rather thickened than dissipated the mystery which hangs over the elements. The discovery of these co-ordinate families dimly points to some identical origin, without suggesting the method of their genesis or the nature of their common parentage. If they were organic beings, all our difficulties would be solved by muttering the comfortable word "evolution"—one of those indefinite words from time to time vouchsafed to humanity, which have the gift of alleviating so many perplexities and masking so many gaps in our knowledge. But the families of elementary atoms do not breed ; and we cannot, therefore, ascribe their ordered difference to accidental variations perpetuated by heredity under the influence of natural selection. The rarity of iodine, and the abundance of its sister, chlorine, cannot be attributed to the survival of the fittest in the struggle for existence. We cannot account for the minute difference which persistently distinguishes nickel from cobalt by ascribing it to the recent inheritance by one of them of an advantageous variation from the parent stock.

The upshot is that all these successive triumphs of research—Dalton's, Kirchoff's, Mendeléeff's—greatly as they have added to our store of knowledge, have gone but little way to solve the problem which the elementary atoms have for centuries presented to mankind. What the atom of each element is—whether it is a movement, or a thing, or a vortex, or a point having inertis ; whether there is any limit to its divisibility, and, if so, how that limit is imposed ; whether the long list of elements is final, or whether any of them have any common origin—all these questions remain surrounded by a darkness as profound as ever. The dreams which lured the alchemists to their tedious labours, and which may be said to have called chemistry into being, has assuredly not been realised, but it has not yet been refuted. The boundary of our knowledge in this direction remains where it was many centuries ago.

The next discussion to which I should look in order to find unsolved riddles which have hitherto defied the scrutiny of science, would be the question of what is called the ether. The ether occupies a highly anomalous position in the world of science. It may be described as a half-discovered entity. I dare not use any less pedantic word than entity to designate it, for it would be a great exaggeration of our knowledge if I were to speak of it as a body or even as a substance. When nearly a century ago Young and Fresnel discovered that the motions of an incandescent particle were conveyed to our eyes by undulation, it followed that between our eyes and the particle there must be something to undulate. In order to furnish that something, the notion of the ether was conceived, and for more than two generations the main, if not the only, function of the word ether has been to furnish a nominative case to the verb "to undulate." Lately, our conception of this entity has received a notable extension. One of the most brilliant of the services which Prof. Maxwell has rendered to science has been the discovery that the figure which expressed the velocity of light, also expressed the multiplier required to change the measure of static or passive electricity into that of dynamic or active electricity. The interpretation reasonably affixed to this discovery is that, as light and the electric impulse move approximately at the same rate through space, it is probable that the undulations which convey them are undulations of the same medium. And as induced electricity penetrates through everything, or nearly everything, it follows that the ether through which its undulations are propagated must pervade all space, whether empty or full, whether occupied by opaque matter or transparent matter, or by no matter at all. The attractive experiments by which the late Prof. Hertz illustrated the electric vibrations of the ether will only be alluded to by me, in order that I may express the regret deeply and generally felt that death should have terminated prematurely the scientific career which had begun with such brilliant promise and such fruitful achievements. But the mystery of the ether, though it has been made more fascinating by these discoveries, remains even more inscrutable than before. Of this all-pervading entity we know absolutely nothing except this one fact, that it can be made to undulate. Whether, outside the influence of matter on the motion of its waves, ether has any effect on matter or matter upon it, is absolutely unknown. And even its solitary function of undulating ether performs in an abnormal fashion which has caused infinite perplexity. All fluids that we know transmit any blow they have received by waves which undulate backwards and forwards in the path of their own advance. The ether undulates athwart the path of the wave's advance. The genius of Lord Kelvin has recently discovered what he terms a labile state of equilibrium, in which a fluid that is infinite in its extent may exist, and may undulate in this eccentric fashion without outraging the laws of mathematics. I am no mathematician, and I cannot judge whether this reconciliation of the action of the ether with mechanical law is to be looked upon as a permanent solution of the question, or is only what diplomatists call a *modus vivendi*. In any case it leaves our knowledge of the ether in a very rudimentary condition. It has no known qualities except one, and that quality is in the highest degree anomalous and inscrutable. The extended conception which enables us to recognise ethereal waves in the vibrations of electricity has added infinite attraction to the study of those waves, but it carries its own difficulties with it. It is not easy to fit in the theory of electrical ether waves with the phenomena of positive and negative electricity, and as to the true significance and cause of those counteracting and complementary forces, to which we give the provisional names of negative and positive, we know about as much now as Franklin knew a century and a half ago.

I have selected the elementary atoms and the ether as two instances of the obscurity that still hangs over problems which the highest scientific intellects have been investigating for several generations. A more striking but more obvious instance still is life—animal and vegetable life—the action of an unknown force on ordinary matter. What is the mysterious impulse which is able to strike across the ordinary laws of matter and twist them for a moment from their path ? Some people demur to the use of the term "vital force" to designate this impulse. In their view the existence of such a force is negatived by the fact that chemists have been able by cunning substitutions to produce artificially the peculiar compounds which in nature are only found in organisms that are or have been living. These compounds are produced by some living organism in the performance of the ordered series of functions proper to its brief career. To counterfeit them—as has been done in numerous cases—does not enable us to do what the vital force alone can effect—to bring the organism itself into existence, and to cause it to run its appointed course of change. This is the unknown force which continues to defy not only our imitation but our scrutiny. Biology has been exceptionally active and successful during the last half-century. Its triumphs have been brilliant, and they have been rich enough, not only in immediate result, but in the promise of future advance. Yet they give at present no hope of penetrating the great central mystery. The progress which has been made in the study of microscopic life has been very striking, whether or not the results which are at present inferred from it can be taken as conclusive. Infinitesimal bodies found upon the roots of plants have the proud office of capturing and taming for us the free nitrogen of the air, which, if we are to live at all, we must consume and assimilate, and yet which, without the help of our microscopic ally, we could not draw for any useful purpose from the ocean of nitrogen in which we live. Microscopic bodies are convicted of causing many of the worst diseases to which flesh is heir, and the guilt of many more will probably be brought home to them in due time ; and they exercise a scarcely less sinister or less potent influence on our race by the plagues with which they destroy some of the most valuable fruits of husbandry, such as the potato, the mulberry, and the vine. Almost all their power

Digitized by Google

resides in the capacity of propagating their kind with infinite rapidity, and up to this time science has been more skilful in describing their ravages than in devising means to hinder them. It would be ungrateful not to mention two brilliant exceptions to this criticism. The antiseptic surgery which we owe chiefly to Lister, and the inoculation against anthrax, hydrophobia, and perhaps some other diseases, which we owe to Pasteur, must be recorded as splendid victories over the countless legions of our infinitesimal foes. Results like these are the great glory of the scientific workers of the past century. Men may perhaps have overrated the progress of nineteenth-century research in opening the secrets of nature, but it is difficult to overrate the brilliant service it has rendered in ministering to the comforts and diminishing the sufferings of mankind.

If we are not able to see far into the causes and origin of life in our own day, it is not probable that we shall deal more successfully with the problem as it arose many million years ago. Yet certainly the most conspicuous event in the scientific annals of the last half-century has been the publication of Mr. Darwin's work on the "Origin of Species," which appeared in 1859. In some respects, in the depth of the impression which it made on scientific thought, and even on the general opinion of the world, its momentous effect can hardly be overstated. But at this distance of time it is possible to see that some of its success has been due to adventitious circumstances. It has had the chance of enlisting among its champions some of the most powerful intellects of our time, and perhaps the still happier fortune of appearing at a moment when it furnished an armoury of weapons to men, who were not scientific, for use in the bitter but transitory polemics of the day. But far the largest part of its accidental advantages was to be found in the remarkable character and qualifications of its author. The equity of judgment, the simple-minded love of truth and the patient devotion to the pursuit of it through years of toil and of other conditions the most unpropitious—these things endeared to numbers of men everything that came from Charles Darwin apart from its scientific merit or literary charm; and whatever final value may be assigned to his doctrine, nothing can ever detract from the lustre shed upon it by the wealth of his knowledge and the infinite ingenuity of his resource. The intrinsic power of his theory is shown at least in this one respect, that in the department of knowledge with which it is concerned it has effected an entire revolution in the methods of research. Before his time the study of living nature had a tendency to be merely statistical; since his time it has become predominantly historical. The consideration how any organic body came to be what it is occupies a far larger area in any enquiry now than the mere description of its actual condition; but this question was not predominant—it may almost be said to have been ignored—in the botanical and zoological study of 60 years ago.

Another lasting and unquestioned effect has resulted from Darwin's work. He has, as a matter of fact, disposed of the doctrine of the immutability of species. It has been mainly associated in recent days with the honoured name of Agassiz, but with him has disappeared the last defender of it who could claim the attention of the world. Few now are found to doubt that animals separated by differences far exceeding those that distinguish what we know as species have yet descended from common ancestors. But there is much less agreement as to the extent to which this common descent can be assumed, or the process by which it has come about. Darwin himself believed that all animals were descended from "at most four or five progenitors," adding that "there was grandeur in the view that life had been originally breathed by the Creator into a few forms or one." Some of his more devoted followers, like Prof. Haeckel, were prepared to go a step farther and to contemplate a crystal as the probable ancestor of the whole fauna and flora of this planet.

To this extent the Darwinian theory has not affected the conquest of scientific opinion, and still less is there any unanimity in the acceptance of natural selection as the sole or even the main agent of whatever modifications may have led up to the existing forms of life. The deepest obscurity still hangs over the origin of the infinite variety of life. Two of the strongest objections to the Darwinian explanation appear still to retain all their force.

I think Lord Kelvin was the first to point out that the amount of time required by the advocates of the theory for working out the process they had imagined could not be conceded without assuming the existence of a totally different set of natural laws from those with which we are acquainted. His view was not only based on profound mechanical reasoning, but it was so plain that any layman could comprehend it. Setting aside arguments deduced from the resistance of the tides, which may be taken to transcend the lay understanding, his argument from the refrigeration of the earth requires little science to apprehend it. Everybody knows that hot things cool, and that according to their substance they take more or less time in cooling. It is evident from the increase of heat as we descend into the earth that the earth is cooling, and we know by experiment, within certain wide limits, the rate at which its substances, the matters of which it is constituted, are found to cool. It follows that we can approximately calculate how hot it was so many million years ago. But if at any time it was hotter at the surface by 50deg. F. than it is now, life would then have been impossible upon the planet, and therefore we can without much difficulty fix a date before which organic life on earth cannot have existed. Basing himself on these considerations, Lord Kelvin limited the period of organic life upon the earth to a hundred million years, and Prof. Tait in a still more penurious spirit cut that hundred down to ten. But on the other side of the account stand the claims of the geologists and biologists. They have revelled in the prodigality of the cyphers which they put at the end of the earth's hypothetical life. Long cribbed and cabined within the narrow bounds of the popular chronology, they have exulted wantonly in their new freeeom. They have lavished their millions of years with the open hand of a prodigal heir indemnifying himself by present extravagance for the enforced self-denial of his youth. But it cannot be gainsaid that their theories require at least all this elbowroom. If we think of that vast distance over which Darwin conducts us from the jelly-fish lying on the primeval beach to man as we know him now; if we reflect that the prodigious change requisite to transform one into the other is made up of a chain of generations, each advancing by a minute variation from the form of its predecessor, and if we further reflect that these successive changes are so minute that in the course of our historical period—say, 3,000 years—this progressive variation has not advanced by a single step perceptible to our eyes, in respect to man or the animals and plants with which man is familar, we shall admit that for a chain of change so vast, of which the smallest link is longer than our recorded history, the biologists are making no extravagant claim when they demand at least many hundred million years for the accomplishment of the stupendous process. Of course, if the mathematicians are right, the biologists cannot have what they demand. If, for the purposes of their theory, organic life must have existed on the globe more than a hundred million years ago, it must, under the temperature then prevailing, have existed in a state of vapour. The jelly-fish would have been dissipated in steam long before he had had a chance of displaying the advantageous variation which was to make him the ancestor of the human race. I see in the eloquent discourse of one of my most recent and most distinguished predecessors in this chair, Sir Archibald Geikie, that the controversy is still alive. The mathematicians sturdily adhere to their figures, and the biologists are quite sure the mathematicians must have made a mistake. I will not get myself into the line of fire by intervening in such a controversy. But until it is adjusted the laity may be excused for returning a verdict of "not proven" upon the wider issues the Darwinian school has raised.

The other objection is best stated in the words of an illustrious disciple of Darwin who has recently honoured this city by his presence—I refer to Prof. Weismann. But in referring to him, I cannot but give, in passing, a feeble expression to the universal sorrow with which in this place the news was received that Weismann's distinguished antagonist, Prof. Romanes, had been taken from us in the outset and full promise of a splendid scientific career.

The gravest objection to the doctrine of natural selection was expressed by Weismann in a paper published a few months ago, not as agreeing to the objection, but as resisting it; and therefore his language may be taken as an impartial statement of the difficulty. "We accept natural selection," he says, "not because we are able to demonstrate the process in detail, not even because we can with more or less ease imagine it, but simply because we must—because it is the only possible explanation that we can conceive. We must assume natural selection to be the principle of the explanation of the metamorphoses, because all other apparent principles of explanation fail us, and it is inconceivable that there could yet be another capable of explaining the adaptation of organisms without assuming the help of a principle of design."

There is the difficulty. We cannot demonstrate the process of natural selection in detail; we cannot even, with more or less ease, imagine it. It is purely hypothetical. No man, so far as we know, has ever seen it at work. An accidental variation may have been perpetuated by inheritance, and in the struggle for existence the bearer of it may have replaced, by virtue of the survival of the fittest, his less improved competitors; but as far as we know no man or succession of men have ever observed the whole process in any single case, and certainly no man has recorded the observation. Variation by artificial selection, of course, we know very well; but the intervention of the cattle breeder and the pigeon fancier is the essence of artificial selection. It is effected by their action in crossing, by their skill in bringing the right mates together to produce the progeniture they want. But in natural selection who is to supply the breeder's place? Unless the crossing is properly arranged, the new breed will never come into being. What is to secure that the two individuals of opposite sexes in the primeval forest, who have been both accidently blessed with the same advantageous variation, shall meet, and transmit by inheritance that variation to their successors? Unless this

Digitized by Google

step is made good, the modification will never get a start, and yet there is nothing to ensure that step except pure chance. The law of chances takes the place of the cattle breeder and the pigeon fancier. The biologists do well to ask for an immeasurable expanse of time, if the occasional meetings of advantageously varied couples from age to age are to provide the pedigree of modifications which unite us to our ancestor, the jelly-fish. Of course the struggle for existence, and the survival of the fittest, would in the long run secure the predominance of the stronger breed over the weaker. But it would be of no use in setting the improved breed going. There would not be time. No possible variation which is known to our experience, in the short time that elapses in a single life between the moment of maturity and the age of reproduction, could enable the varied individual to clear the field of all competitors either by slaughtering or starving them out. But unless the struggle for existence took this summary and internicine character, there would be nothing but mere chance to secure that the advantageously varied bridegroom at one end of the wood should meet the bride, who by a happy contingency had been advantageously varied in the same direction at the same time at the other end of the wood. It would be a mere chance if they ever knew of each other's existence—a still more unlikely chance that they should resist on both sides all temptations to a less advantageous alliance. But unless they did so, the new breed would never even begin, let alone the question of its perpetuation after it had begun. I think Prof. Weismann is justified in saying that we cannot, either with more or less ease, imagine the process of natural selection.

It seems strange that a philosopher of Prof. Weismann's penetration should accept as established a hypothetical process the truth of which he admits that he cannot demonstrate in detail, and the operation of which he cannot even imagine. The reason that he gives seems to me instructive of the great danger scientific research is running at the present time—the acceptance of mere conjecture in the name and place of knowledge, in preference to making frankly the admission that no certain knowledge can be attained. "We accept natural selection," he says, "because we must—because it is the only possible explanation that we can conceive." As a politician I know that argument very well. In political controversy it is sometimes said of a disputed proposal that it "holds the field," that it must be accepted because no possible alternative has been suggested. In politics there is occasionally a certain validity in the argument, for it sometimes happens that some definite course must be taken, even though no course is free from objection. But such a line of reasoning is utterly out of place in science. We are under no obligation to find a theory, if the facts will not provide a sound one. To the riddles which nature propounds to us the profession of ignorance must constantly be our only reasonable answer. The cloud of impenetrable mystery hangs over the development and still more over the origin of life. If we strain our eyes to pierce it, with the foregone conclusion that the solution is and must be attainable, we shall only mistake for discoveries the figments of our own imagination. Prof. Weismann adds another reason for his belief in natural selection which is certainly characteristic of the time in which we live. "It is inconceivable," he says, "that there should be another principle capable of explaining the adaptation of organisms without assuming the help of a principle of design." The whirligig of time assuredly brings its revenges. Time was, not very long ago, when the belief in creative design was supreme. Even those who were sapping its authority were want to pay it a formal homage, fearing to shock the public conscience by denying it. Now the revolution is so complete that a great philosopher uses it as a *reductio ad absurdum*, and prefers to believe that which can neither be demonstrated in detail nor imagined, rather than run the slightest risk of such a heresy.

I quite accept the professor's dictum that if natural selection is rejected we have no resource but to fall back on the mediate or immediate agency of a principle of design. In Oxford, at least, he will not find that argument is conclusive, nor, I believe, among scientific men in this country generally, however imposing the names of some whom he may claim for that belief. I would rather lean to the conviction that the multiplying difficulties of the mechanical theory are weakening the influence it once had acquired. I prefer to shelter myself in this matter behind the judgment of the greatest living master of natural science among us, Lord Kelvin, and to quote as my own concluding words the striking language with which he closed his address from this chair more than 20 years ago: "I have always felt," he said, "that the hypothesis of natural selection does not contain the true theory of evolution, if evolution there has been in biology. . . . I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Overpoweringly strong proofs of intelligent and benevolent design lie around us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back upon us with irresistible force, showing to us through nature the influence of a free will, and teaching us that all living things depend on one everlasting Creator and Ruler."

Address to the Mathematical and Physical Section.

BY PROF. A. W. RÜCKER, M.A., F.R.S, PRESIDENT OF THE SECTION.

It is impossible for a body of English scientific men to meet in one of our ancient university towns without contrasting the old ideal of the pursuit of learning for its own sake with the modern conception of the organisation of science as part of a pushing business concern. We are, as a nation, convinced that education is essential to national success. Our modern universities are within earshot of the whirr of the cotton-mill or the roar of Piccadilly. Oxford and Cambridge themselves are not content to be centres of attraction to which scholars gravitate. They have devised schemes by which their influence is directly exerted on every market town and almost on every village in the country. University extension is but a part of the extraordinary multiplication of the machinery of education which is going on all around us. The British Association, which was once regarded as bringing light into dark places, is now welcomed in every large provincial town by a group of well-known men of science; and we find ready for the meetings of our sections not only the chapels and concert-rooms which have so often and so kindly been placed at our disposal, but all the appliances of well-designed lecture-rooms and laboratories.

I do not propose, however, to detain you this morning with a discourse on the spread of scientific education, but you will forgive me if I illustrate its progress by two facts, not perhaps the most striking which could be selected, but especially appropriate to our place of meeting. It is little more than 30 years since the two branches of science with which our section deals—mathematics and physics—have been generally recognised as wide enough to require more than one teacher to cope with them in an educational institution of high pretensions and achievement. In 1860 the authorities of the Owens College, Manchester, debated whether it was desirable to create a professorship of natural philosophy in addition to, and independent of, the chair of mathematics. It was thought necessary to obtain external support for the opinions of those who advocated this step. An appeal was made to Profs. De Morgan and Stokes. The former reported that a "course of experimental physics is in itself desirable"; the latter, that "there would be work enough in a large institution for a mathematician and a physicist." In the end the chair of natural philosophy was established, and the fact that our host of to-day, Prof. Clifton, was its first occupant reminds us how little we have advanced in time and how far in educational development from the days when propositions such as those I have cited were only accepted on the authority of the names of Stokes and De Morgan. The other fact to which I would refer is that the Clarendon Laboratory, in which the meetings of Section A are to be held, though erected barely a quarter of a century ago, was the first laboratory in this country which was specially built and designed for the study of experimental physics. It has served as a type. Clerk Maxwell visited it while planning the Cavendish Laboratory, and traces of Prof. Clifton's designs can be detected in several of our university colleges.

But though our surroundings remind us of the improvement which has been effected in the equipment of our science, it would not be difficult to indicate weak points which should forthwith be strengthened. On these, in so far as they affect education, I will not dwell—and that for two reasons. In the first place, we meet not to-day as teachers, but as students; and secondly, I think that whereas as a nation we have awoke—though late in the day—to the importance of education, we are not yet fully awake to the importance of learning. Our attitude in such matters was exactly expressed by one of the most eminent of the witnesses who gave evidence before the Gresham Commission. In his opinion the advancement of knowledge must in a university in London be secondary to the higher instruction of the youth of London. If this be so—and I will not now dispute it—we shall surely all agree that somewhere or other, in London or out of it, included in our universities or separate from them, there ought to be institutions in which the advancement of knowledge is regarded as of primary and fundamental interest, and not as a mere secondary by-product thrown off in the course of more important operations.

It is not essential that in such an institution research should be the only task. Investigation may be combined with the routine work of an observatory, with teaching, with the care of standards, or with other similar duties. It is, however, essential that if the advancement of knowledge is seriously regarded as an end worth attaining, it should not be relegated to a secondary place. Time and opportunity must be found for investigation, as time and opportunity are found for other tasks. It is not enough to refer to research in a prospectus and then to leave it to be accomplished at odd times and in spare moments not claimed by more urgent demands. Those to whom the future of the higher learning in England is dear must plan and scheme

Digitized by Google

to promote the life-long studies of men, as in the last quarter of a century they have struggled, with marked success, to promote the preparatory studies of boys and girls. That the assignment of a secondary position to research is the more popular view, and that the necessity for encouraging it has as yet hardly been grasped by many of those who control our modern educational movements is, I fear, too true. It is therefore a matter for congratulation that within the last year Oxford has established a research degree, and has thus taken an important step towards gathering within her fold workers of mature years who are able and willing not merely to gain knowledge, but to add to it. We may also note with pleasure and gratitude that the stream of private munificence has recently been in part directed to the advancement of learning. Sir Henry Thompson has generously offered a sum of £5,000 to provide a large photographic telescope for the National Observatory at Greenwich. The new instrument is to be of 26in. aperture and 22ft. 6in. focal length, or exactly double the linear dimensions of that which has been previously employed. Mr. Ludwig Mond, too, has added to his noble gifts to science by the new research laboratories which he is about to establish in connection with the Royal Institution. Albemarle-street is thronged with memories of great discoveries. The researches of Lord Rayleigh and the remarkable results of Prof. Dewar's studies of matter at low temperatures are maintaining the great reputation which the Royal Institution has gained in the past, and all English physicists will rejoice that prospects of new and extended usefulness are opening before it.

Another hopeful, though very embarrassing, fact is that the growth in the number of scientific workers makes it increasingly difficult to find the funds which are necessary for the publication of their work. Up to the present the author of a paper has had to submit it to criticism, but, when it has been approved by competent judges, it has been published without ado and without expense to himself. This is as it should be. It is right that due care should be exercised to prune away all unnecessary matter, to reduce as far as may be the necessary cost. It will, however, be a great misfortune if judgment as to what curtailment is necessary is in future passed, not with the object of removing what is really superfluous, but in obedience to the iron rule of poverty. Apart from all other disadvantages, such a course would add to the barriers which are dividing the students of different sciences. A few lines and a rough diagram may suffice to show to experts what has been attempted and what achieved, but there is no paper so difficult to master as that which assumes that the reader starts from the point of vantage which months or years of study have enabled the author to attain. Undue pruning will not make the tree of knowledge more fruitful, and will certainly make it harder to climb. Connected also with the vast increase of scientific literature is a growing necessity for the publication of volumes of abstracts, in which the main results of recent investigations are presented in a concentrated form. English chemists have long been supplied with these by the Chemical Society. The Physical Society, though far less wealthy than its elder sister, has determined to undertake a similar task. We are compelled to begin cautiously, but in January next the first number of a monthly pamphlet will be issued containing abstracts of all the papers which appear in the principal foreign journals of physics. In this venture the society will incur grave responsibilities, and I avail myself of this opportunity to appeal to all British physicists to support us in a work the scope of which will be rapidly extended if our first efforts succeed.

From this brief glance at what has been or is about to be done to promote the study of physics, I must now turn to the discussion of narrower but more definite problems, and I presume that I shall be most likely to deserve your attention if I select a subject in which I am myself especially interested. During the last 10 years my friend Dr. Thorpe and I have been engaged upon a minute magnetic survey of the United Kingdom. The main conclusions at which we have arrived are about to be published, and I do not propose to recount them now. It is, however, impossible to give so long a time to a single research without having one's attention drawn to a number of points which require further investigation, and I shall perhaps be making the best use of this opportunity if I bring to your notice some matters in the practical and theoretical study of terrestrial magnetism which deserve a fuller consideration than has yet been given to them. In the first place, then, there is little doubt that the instruments at present used for measuring declination and horizontal force are affected with errors far greater than the error of observation. We employed four magnetometers by Elliott Bros., which were frequently compared with the standard instrument at Kew. These measurements proved that the instrumental differences which affect the accuracy of the declination and horizontal force measurements are from five to ten times as great as the error of a single field observation. The dip circle which two generations ago was so untrustworthy is, in our experience, the most satisfactory of the absolute instruments. In most cases these comparisons extended over several days, but the Astronomer Royal has described in his recent report observations made at Greenwich for two years and a half with two horizontal force instruments. These differ between themselves, and the discrepancy is of the same order of magnitude as those we have detected. If such differences exist between instruments of the Kew pattern, it is probable that they will be still greater when the magnetometers under investigation are of different types. This point has been investigated by Dr. Van Rijckevorsel, who five years ago visited Kew, Parc St. Maur, Wilhelmshaven, and Utrecht, and, using his own instruments at each place, compared the values of the magnetic elements determined by himself with those deduced from the self-registering apparatus of the observatory. The discrepancies between the so-called standards which were thus brought to light were quite startling, and prove the necessity for an investigation as to their causes.

Magneticians had long been aware that the instruments used by travellers should be compared at the beginning and end of a journey with those at some fixed observatory, to make sure that the comparatively rough usage to which they are subjected has not affected their indications. But Dr. Van Rijckevorsel's expedition first drew general attention to the fact that there are serious differences between the standard observatory instruments themselves. The importance of a careful comparison between them was at once recognised. The Magnetic Sub-Committee of the International Meteorological Conference, held at Munich in the autumn of 1891, resolved that it is "necessary that the instruments employed for absolute measurements at the different observatories should be compared with each other and the results published." As far as I am aware nothing has been done to give effect to this resolution, but the necessity for such an international comparison is urgent. The last few years have been a period of unexampled activity in the conduct of local magnetic surveys. To cite instances from the north-west of Europe only, observations have recently been made on a more or less extended scale in the United Kingdom, France, Holland, North Germany, and Denmark. It will be absurd if these surveys cannot be collated and welded into a homogeneous whole, because we are in doubt whether the indications of our standard instruments for the measurement of declination and dip differ by five or six minutes of arc. If, however, an official international comparison of the magnetic standards in use in different countries is instituted, it is probable that only one observatory in each country will take part in it. It may fairly be left to each nation to determine for itself the relations between the results of measurements made in its own institutions. Apart, therefore, from all other reasons, we in England would only be able to make the best use of an international comparison if we had beforehand set our own house in order, and were able at once to extend the results of experiments made at Kew or Greenwich to Stonyhurst, Valentia, and Falmouth. This we are not at the present moment in a position to do. As far as I know, nobody has ever carried a magnetometer backwards and forwards between Kew and Greenwich to test the concordance of the published results. During the recent survey single or double sets of observations have been made at Stonyhurst, Falmouth, and Valentia with instruments which have been compared with Kew, but these measurements, though amply sufficient for the purposes of our research, were not numerous enough to serve as a firm basis for determining the discrepancies between the various standards, so that the exact relations between these important sets of apparatus are still unknown.

The first point, therefore, to which I wish to draw the attention of the section is the necessity for a full primary comparison between the standard magnetic instruments in use at our different observatories. But if this were satisfactorily accomplished, the question would arise as to whether it should be repeated at regular intervals. We have at present only a presumption in favour of the view that the standards which we know are discordant are nevertheless constant. A single instance may suffice to show how necessary it may be—at all events in the case of outlying and isolated observatories—to put this belief to the test. In the most recent account of the work of the observatory of the Bombay Government at Colába, the dips are discussed for the period of 20 years between 1872 and 1892. During this interval the adjustment of the agate plates upon which the dip needle rolls has thrice been modified. In 1877 the plates were renewed. In 1881 and 1887 the dip circle was taken to pieces and rebuilt. In the intervals the dip as determined by several needles, but always with this circle, remained approximately constant, but after each overhauling it suddenly altered, increasing by 12′ on the first occasion, by 23′ on the second, and by 20′ on the third. Mr. Chambers states that he "can give no satisfactory account of this behaviour of the instrument," but suggests that "the needle gradually hollows out a depression in the agate plates on which it rolls, and that this characteristic of the dip circle" has not before been discovered owing to the reluctance of magnetic observers to interfere with the adjustments of instruments which are apparently working well. I do not think that this explanation will suffice. Dr. Thorpe and I employed a new dip circle in the earliest part of our survey work, which has remained in accord with Kew for 10 years.

Digitized by Google

During that time the dip has been measured some 700 times with it. This corresponds, I believe, to more than the amount of work done with the circle at Colába in six years, which in turn is longer than some of the intervals in which the Colába instruments gave results erroneous to the extent of 20′. I feel, therefore, quite sure that the difficulties which have been experienced at Bombay are not due to any "characteristic [defect] of the dip circle." But, whatever the cause may have been, surely the lesson is that, if such things can happen in so well known an institution, it is desirable that we should take the moderate pains required to assure ourselves whether smaller—but, possibly, not unimportant—errors are gradually affecting the results at any of our observatories.

This brings me to my next point—namely, that if we are to draw conclusions from the minor differences between measurements of secular or diurnal change made in the observatories, it is not only necessary that we should know whether the instruments are strictly comparable and constant, but the observations must be reduced by precisely the same methods. In 1886 the late Mr. Whipple drew the attention of the British Association to the fact that there was a systematic difference between the diurnal ranges of declination at Greenwich and Kew. His results were based on the three years 1870-72. In 1890 two of my students, Messrs. Robson and S. W. J. Smith, extended the comparison to three more recent years (1883-6-7), and obtained results in complete accord with those of Mr. Whipple. It is well known that the average daily oscillation of the magnet is affected by the magnetic weather. Sabine showed that magnetic storms do not merely buffet the needle now in this direction and now in that—they affect its average behaviour, so that the mean swing east and west is different according as we deduce it only from days of magnetic calm or include those of storm. Mr. Whipple reduced the Kew observations by two methods,* one of which depended on the calmest days only, while the other included those which were moderately disturbed. Neither agreed exactly with the method in use at Greenwich, but the difference between the results deduced from them was so small when compared with the difference between either and that obtained at Greenwich, that it seemed possible that the diurnal variations, even at these closely neighbouring places, might differ appreciably. The question whether this is so has now been answered. In 1890, at the request of the Kew Committee, the Astronomer Royal undertook to select early in each year five quiet days in each of the preceding 12 months. It was also agreed that, whether they adopted other methods or not the chief English magnetic observatories should determine the diurnal variations from these days alone. The Greenwich† and Kew observations for 1890 have therefore been worked up in exactly the same way, with the result that the discrepancy, which had persisted for 20 years, has entirely disappeared, and that the two diurnal ranges at the two observatories are in as close accord as could be expected. If, therefore, we may judge from a single year, the cause of the difference lay in the choice of days. Greenwich will in future give us two diurnal variations, one obtained from the most quiet days only, the other from all days except those of violent storm, and in these we shall have most valuable data for studying the mean effect of disturbances on the diurnal variation. To this satisfactory conclusion I have only one suggestion to add. The Astronomer Royal and M. Mascart now publish for the same stormy days the photographic traces by which the history of a magnetic storm is mapped. Is it possible for Greenwich and Paris also to agree in their choice of calm days for the calculation of the diurnal variation, so that a precise similarity of method may obtain not only between the English observatories, but between England and France?

The importance of co-operation between institutions engaged on the same tasks having been illustrated, I am glad to be able to announce that another step is about to be taken in the same direction. For some years, in spite, I believe, of great financial difficulties, the Cornwall Royal Polytechnic Society has maintained a magnetic observatory at Falmouth. The results of the observations have hitherto been printed in the *Journal* of the society only, out the Royal Society has now consented to publish them in the *Proceedings*. Before long, therefore, the Kew and Falmouth records, which are already worked up in the same way, will be given to the world side by side. Is it too much to hope that this may be the first step towards the production of a British magnetic year-book, in which observations whose chief interest lies in their comparison may be so published as to be easily compared? We owe to private enterprise another advance of the same kind. The managers of the new journal, *Science Progress*, have made arrangements with the Kew Committee for the yearly publication of a table showing the mean annual values of the magnetic elements as determined at the various magnetic observatories of the world. It will, therefore, in future be possible to get a general idea of the rate of secular change in different localities without searching through a number of reports in different languages, which can only be consulted in the rooms of the few societies or institutions to which they are annually sent. The present state of our knowledge of the secular change in the magnetic elements affords indeed very strong support to the arguments I have already adduced in favour of a comparison between the instruments of our magnetic observatories.

The whole question of the cause of this phenomenon has entered on a new stage. It has long been recognised that the earth is not a simple magnet, but that there are in each hemisphere one pole or point at which the dip needle is vertical, and two foci of maximum intensity. A comparison of earlier with later magnetic observations led to the conclusion that one or both of the foci in each hemisphere is in motion, and that to this motion—however caused—the secular change in the values of the magnetic elements is due. Thus, the late Prof. Balfour Stewart, writing in 1883, says: "While there is no well-established evidence to show that either the pole of verticity or the centre of force to the North of America has perceptibly changed its place, there is, on the other hand, very strong evidence to show that we have a change of place on the part of the Siberian focus."* The facts in favour of this conclusion are there discussed. The arguments are based, not on the results of any actual observations near to the focus in question, but on the behaviour of the magnet at points far distant from it in Europe and Asia. The westerly march of the declination needle, which lasted in England up to 1818, and the easterly movement which has since replaced it, are connected with a supposed easterly motion of the Siberian focus, which, it is added, "there is some reason to believe . . . has recently been reversed." In opposition, therefore, to the idea of the rotation of a magnetic focus round the geographical poles which the earlier magneticians adopted, Stewart seems to have regarded the motion of the Siberian focus as oscillatory. A very different aspect is put upon the matter by a comparison of the magnetic maps of the world prepared by Sabine and Creak for the epochs 1840 and 1880 respectively. Captain Creak, having undertaken to report on the magnetic observations made during the voyage of the "Challenger," supplemented them with the unrivalled wealth of recorded facts at the disposal of the Hydrographic Department of the Admiralty. He was thus able, by a comparison with Sabine's map, to trace the general course of the secular changes all over the world for 40 years. The negative results may be shortly stated. There is no evidence of any motion either of magnetic pole or focus. The positive conclusions are still more curious. There are certain lines on the surface of the earth towards which in the interval under consideration the north pole of the needle was attracted. From each side the compass veered or backed towards them. Above them the north pole of dip needle moved steadily down. There are other lines from which, as tested by compass and dip circle, a north pole was in like manner repelled. The two principal points of increasing attraction are in China and near Cape Horn; the chief points of growing repulsion are in the North of Canada and the Gulf of Guinea. I am sure that my friend Captain Creak would be the first to urge that we should not generalise too hastily from this mode of presenting the facts, but there can be no doubt that they cannot be explained by any simple theory of a rotating or oscillating pair of poles. *Primâ facie* they suggest that the secular change is due not so much to changes at the principal magnetic points, as to the waxing and waning of the forces apparently exerted by secondary lines or points of attraction or repulsion. All down the west coast of America, close, be it noted, to one of the great lines of volcanic activity, north hemisphere magnetism has since 1840 been growing in relative importance. Near Cape Horn a weak embryonic pole is developing of the same kind as the well-known pole at the other end of the continent near Hudson's Bay. Along a line which joins Newfoundland to the Cape of Good Hope, precisely the reverse effects have been experienced; while in the Gulf of Guinea a south hemisphere pole is growing within the tropics. Of course, I do not suggest that these secondary systems can ever determine the principal phenomena of terrestrial magnetism, or reverse the magnetic states of the hemispheres in which they occur. These are no doubt fixed by the rotation of the earth. I do, however, wish to emphasise the fact that they show that either secular change is due to the conjoint action of local causes, or that if some single agent such as a current system within the earth, or a change of magnetic conditions outside it, be the primary cause, the effects of this cause are modified and complicated by local peculiarities. Mr. Henry Wilde has succeeded in representing with approximate accuracy the secular change at many points on the surface of the earth by placing two systems of currents within a globe, and imparting to the axis of one of them a motion of rotation about the polar axis of the earth. But he has had to supplement this comparatively simple arrangement by local features. He has coated the seas with thin sheet iron. The ratio between the two currents which serves to depict the secular change near the meridian of Greenwich fails in the West Indies. Thus this ingenious attempt to imitate the secular change by a

* Sabine's and Wild's.

Digitized by Google

simple rotation of the magnetic pole supports the view that local peculiarities play a powerful part in modifying the action of a simple first cause, if such exist. I need hardly say that I think the proper attitude of mind on this difficult subject is that of suspended judgment, but there is no doubt that recent investigation has, at all events, definitely raised the question how far secular change is either due to or modified by special magnetic features of different parts of the earth.

It is possible that light may be thrown upon this point by observations on a smaller scale. Assuming for the moment that the difference in the secular changes on opposite sides of the Atlantic is due to a difference of local causes, it is conceivable that similar causes, though less powerful and acting through smaller ranges, might produce similar though less obvious differences between places only a few miles apart. For testing this Greenwich and Kew are in many respects most favourably situated. Nowhere else are two first-class observatories so near together. Differences in the methods of publishing the results have made it somewhat difficult to compare them, but the late Mr. Whipple furnished me with figures for several years which made comparison easy. Without entering into details it may be sufficient to say that the declination needles at the two places do not from year to year run parallel courses. Between 1880-82 Kew outstripped its rival, between 1885 and 1889 it lost, so that the gain was rather more than compensated. The difference of the declination of the two places appears to increase and diminish through a range of five minutes of arc. This evidence can be supplemented by other equally significant examples. No fact connected with terrestrial magnetism is more certain than that at present the rate of secular change of declination in this part of Europe increases as we go north. This is shown by a comparison of our survey with those of our predecessors 50 and 30 years ago, by M. Moureaux's results in France, and by Captain Creak's collation of previous observations. Yet, in spite of this, Stonyhurst. which is some 200 miles north of Greenwich and Kew, and should therefore outrun them, sometimes lags behind and then makes up for lost time by prodigious bounds. Between 1882 and 1886 the total secular change of declination at Stonyhurst was about 3′·5 less than at Greenwich and Kew, whereas in the two years 1890-92 it reached at Stonyhurst the enormous amount of 28′, just doubling the corresponding alteration registered in the same time at Kew. If these fluctuations are caused by the instruments or methods of reduction my argument in favour of frequent comparisons and uniform treatment would be much strengthened, but, apart from the inherent improbability of such large differences being due to the methods of observation, the probability of their physical reality is increased by the work of the magnetic survey.

The large number of observations at our disposal has enabled us to calculate the secular change in a new way, by taking the means of observations made about five years apart at numerous though not identical stations scattered over districts about 150 miles square. The result thus obtained should be free from mere local variations, but as calculated for the south-east of England for the five years 1886-91 it differs by nearly 5′ from the change actually observed at Kew. We have also determined the secular change at 25 stations by double sets of observations made as nearly as possible on the same spot at intervals of several years. The results must be interpreted with caution. In districts such as Scotland, where strong local disturbances are frequent, a change of a few yards in the position of the observer might introduce errors far larger than the fluctuations of secular change. But when all such cares are eliminated, when all allowance is made for the possible inaccuracy of field observations, there are outstanding variations which can hardly be due to anything but a real difference in the rate of change of the magnetic elements. A single example will suffice. St. Leonards and Tunbridge Wells are about 30 miles apart. Both are situated on the Hastings sand formation, and on good non-magnetic observing ground. At them, as at the stations immediately around them—Lewes, Eastbourne, Appledore, Etchingham, Heathfield, and Maidstone—the local disturbing forces are very small. All these places lie within a district about 40 miles square, at no point of which has the magnet been found to deviate by 5′ from the true magnetic meridian. No region could be more favourably situated for the determination of the secular change, yet according to our observations the alteration in the declination at St. Leonards in six years was practically equal to that at Tunbridge Wells in five. It is difficult to assign so great a variation to an accumulation of errors, and this is only one amongst several instances of the same kind which might be quoted. We find, then, when we consider the earth as a whole, grave reason to question the old idea of a secular change caused by a magnetic pole or focus pursuing an orderly orbit around the geographical axis of the earth, or oscillating in some regular period in its neighbourhood. It would, of course, be absurd to admit the possibility of change in the tropics and to deny that possibility in the arctic circle, but the new facts lead us to look upon the earth not as magnetically inert, but as itself—at the equator as well as at the pole—producing or profoundly modifying the influences which give rise to secular change. And then, when we push our enquiry further, accumulating experience tells the same tale. The earth seems, as it were, alive with magnetic forces, be they due to electric currents or to variations in the state of magnetised matter. We need not now consider the sudden jerks which disturb the diurnal sweep of the magnet, which are simultaneous at places far apart, and probably originate in causes outside our globe. But the slower secular change, of which the small part that has been observed has taken centuries to accomplish, is apparently also interfered with by some slower agency, the action of which is confined within narrow limits of space. Between Kew, Greenwich, and Stonyhurst, between St. Leonards and Tunbridge Wells, and I may add between Mablethorpe and Lincoln, Enniskillen and Sligo, Charleville and Bantry, the measured differences of secular variation are so large as to suggest that we are dealing not with an unruffled tide of change, which, unaltered by its passage over continent or ocean, sweeps slowly round the earth, but with a current fed by local springs or impeded by local obstacles, furrowed on the surface by billows and eddies, from which the maguetician, if he will but study them, may learn much as to the position and meaning of the deeps and the shallows below. But if this is the view which the facts I have quoted suggest, much remains to be done before it can be finally accepted; and in the first place—to come back to the point from which I started—we want, for some years at all events, a systematic and repeated comparison of the standard instruments in use at the different observatories. That they are not in accord is certain; whether the relations between them are constant or variable is doubtful. If constant, the suggestions I have outlined are probably correct; if variable, then the whole or part of the apparent fluctuations of secular change may be nothing more than the irregular shiftings of inconstant standards. I cannot myself believe that this is the true explanation, but in any case it is important that the doubt should be set at rest, and that if the apparent fluctuations of secular change are not merely instrumental, the enquiry as to their cause should be undertaken in good earnest.

The question is interesting from another point of view. It is now fully established that even where the surface soil is non-magnetic, and even where geologists have every reason to believe that it lies upon non-magnetic strata of great thickness, there are clearly-defined lines and centres towards which the north-seeking pole of a magnet is attracted, or from which it is repelled. To the magnetic surveyor fluctuations in secular change would appear as variations in the positions of these lines, or as changes in the forces in play in their neighbourhood. Greenwich and Kew are both under the influence of a widespread local disturbance which culminates near Reading. At both places the needle is deviated to the west of the normal magnetic meridian, and if the westerly declination diminishes sometimes faster and sometimes more slowly at one observatory than at the other, this must be, or at all events would in the first instance appear to be due to local changes in the regional disturbing forces. The questions of the nature of the irregularities of secular change and of the causes of local disturbances are therefore intermingled, and information gained on these points may in turn be useful in solving the more difficult problem of world-wide secular variations. Two causes of regional and local disturbances have been suggested—viz., earth currents, and the presence of visible or concealed magnetic rocks. The two theories are not mutually exclusive. Both causes of the observed effects may, and probably do, coexist. I have, however, elsewhere explained my reasons for believing that the presence of magnetic matter, magnetised by induction in the earth's field, is the principal cause of the existence of the magnetic ridge lines and foci of attraction which for so many years we have been carefully tracing. I will only now mention what appears to me to be the final and conclusive argument, which, since it was first enunciated, has been strengthened by the results of our more recent work. We find that every great mass of basic rock, by which the needle is affected at considerable distances, attracts the north-seeking pole. Captain Creak some years ago showed that the same statement is true of those islands in the northern hemisphere which disturb the lines of equal declination, while islands in the southern hemisphere repel the north pole and attract the south. In other words, these disturbances are immediately explained if we suppose that they are due to magnetic matter magnetised by induction. The theory of earth currents would, on the other hand, require that round the masses of visible basalt, and round the island investigated by Captain Creak, currents, or eddies in currents, should circulate in directions which are always the same in the same hemisphere, and always opposed on opposite sides of the equator. For this supposition no satisfactory explanation is forthcoming, and therefore, with all reserves and a full consciousness that in such matters hypothesis differs but little from speculation, it appears to me that the theory that induced magnetism is the main cause of the disturbance has the greater weight of evidence in its favour. If this be granted, it is evident that the positions of the main lines and centres of attraction would be approximately constant, and, so far as it is possible to form an opinion, these conditions

Digitized by Google

seem to be satisfied. There has certainly been no noticeable change in the chief loci of attraction in the five years which have elapsed between the epochs of our two surveys. Mr. Welsh's observations made in Scotland in 1857-8 fit in well with our own. Such evidence is not, however, inconsistent with minor changes, and it is certain that as the directions and magnitude of the inducing forces alter, the disturbing induced forces must alter also. But this change would be slow, and as the horizontal force is in these latitudes comparatively weak, the change in the disturbing forces would also be small, unless the vertical force altered greatly. It is at all events impossible to attribute to this cause oscillations which occupy at most eight or ten years. It is possible to suggest other changes in the state of the concealed magnetic matter—alterations of pressure, temperature, and the like—to which the oscillations of secular change might be due, but probably there will be a general consensus of opinion that if the slowly changing terms in the disturbance function are due to magnetic matter, the more rapid fluctuations of a few years' period are more likely to be connected with earth currents. It becomes, therefore, a matter of interest to disentangle the two constituents of local disturbances; and there is one question to which I think an answer might be obtained without a greater expenditure than the importance of the investigation warrants. Are the local variations in secular change waves which move from place to place, or are they stationary fluctuations, each of which is confined to a limited area beyond which it never travels? Thus, if the annual decrease in the declination is at one time more rapid at Greenwich than at Kew, and five years afterwards more rapid at Kew than at Greenwich, has the maximum of rapidity passed in the interval through all intervening places, or has there been a dividing line of no change which has separated two districts which have perhaps been the scenes of independent variations? The answer to this question is, I take it, outside the range of our knowledge now, but if the declination could be determined several times annually at each of a limited number of stations in the neighbourhood of London, to this enquiry, at all events, a definite answer would soon be furnished.

There are two other lines of investigation which I hope will be taken up sooner or later, for one of which it is doubtful whether the United Kingdom is the best site, while the other is of uncertain issue. If, however, it be granted that the principal cause of local and regional magnetic disturbances is the magnetisation by the earth's field of magnetic matter concealed below its surface, the question as to the nature of this material still remains to be solved. Is it virgin iron or pure magnetite, or it is merely a magnetic rock of the same nature and properties as the basalts which are found in Skye and Mull? There is, of course, no *à priori* reason why all these different materials should not be active, some in one place and some in another. As regards the United Kingdom, I have, both in a paper on the "Permeability of Magnetic Rocks," and in the description of the recent survey, made calculations which tend to prove that if we suppose that the temperature of the interior of the earth is, at a depth of 12 miles, such as to deprive matter of its magnetic properties, and if we further make the unfavourable assumption that down to that limit the susceptibility is constant, the forces which are observed on the surface are of the same order of magnitude as those which could be produced by large masses of ordinary basalt or gabbro. It would not, however, be wise to generalise this result, and to assume that in all places regional disturbances are due to basic rocks alone. We know that local effects are produced by iron ore, for the Swedish miners seek for iron with the aid of the magnet, and in some other cases magnetic disturbances of considerable range are so intense as to suggest that material of very high magnetic permeability must be present. If the concealed magnetic matter were iron, and if it were present in large quantity, it is evident that the results of experiments with the magnetometer and dip circle might be supplemented by observations made with the plumb-line or pendulum. In such a case the region of magnetic disturbance would also be a region of abnormal gravitational attraction. An account of a suggested connection between anomalies of these two kinds occurring in the same district has lately been published by Dr. Fritsche.*

Observations made about 30 years ago by a former director of the Astronomical Observatory in Moscow led to the conclusion that throughout two large districts to the north and south of that city the plumb-line is deviated in opposite directions. The deflections from the vertical are very considerable, and indicate a relative defect in the attraction exerted by the rocks in the neighbourhood of Moscow itself, and the suggestion has been made that there is either a huge cavity—a bubble in the earth-crust—under the town, or that the matter beneath it is less dense than that which underlies the surface strata on either side at a distance of 10 or 12 miles. As long ago as 1853, Captain Meyen made magnetic observations in order to determine whether the same district is also the seat of any magnetic irregularity. His stations were hardly sufficiently numerous to lead to decisive results, but the magnetic elements have recently been measured by Dr. Fritsche at 31 places within 50 miles of Moscow. The experiments were all made within 11 days, so that no correction for secular change is required. They indicate a locus of magnetic attraction running through Moscow itself. South of the town the disturbance again changes in direction so as to show either that repulsive forces are in play, or that there is another magnetic ridge line still further to the south. Dr. Fritsche thinks that these observations explain the gravitational anomalies without recourse to the somewhat forced hypothesis of a vast subterranean cave. He assumes that there is a concealed mass of iron, which approaches near to the surface at Moscow, and also along two loci to the south and north of the city. He attributes the magnetic irregularities to the attraction of the central iron hill, the deflections of the plumb-line to the flanking masses. It is perhaps not inconceivable that such results might follow in a special case, but without the support of calculation it certainly appears that the magnetic experiments point to the existence of the principal attracting mass under the town. This is, in fact, the arrangement shown in the figure with which Dr. Fritsche illustrates his hypothesis. If this is so, the theory would *primâ facie* seem to require that the bob of a plumb-line should be attracted towards, and not, as is actually the case, away from, the centre of the magnetic disturbance. On the whole, then, though the coexistence of large magnetic and gravitational disturbances in the same place is suggestive, I do not think that they have as yet been proved to be different effects of the same hidden mass of magnetic matter. In a few weeks an international geodetic conference will meet at Innsbruck, at which the Royal Society will be represented. It is, I believe, intended to extend the detailed investigation of the relations between the nature of the earth's crust and the gravitational and magnetic forces to which it gives rise. We may therefore hope that special attention will before long be given to localities where both may combine to give information as to facts outside the range of the ordinary methods of geology.

The second phenomenon on which more light is desirable is the permanent magnetisation of magnetic rocks. It is known that fragments of these are strongly but irregularly magnetised, but that the effect of very large masses at a distance appears to be due to induced rather than to permanent magnetism. There are three questions to which I should like an answer. Are underground masses of magnetite ever permanently magnetised? Are large areas of surface masses, say a few hundred square yards in extent, ever permanently and approximately uniformly magnetised in the same sense? Is there any relation between the geological age and the direction of the permanent magnetism of magnetic rocks? Enquiries such as these can only be taken up by individual workers, but I venture to think that the comparison of the observatory instruments and the fluctuations of secular change outside the observatories could best be investigated under the auspices of a great scientific society. The co-operation of the authorities of the observatories will no doubt be secured, but it is most important that the comparisons should in all cases be made with one set of instruments, and by the same methods. Whether the British Association, which for so long managed a magnetic observatory, may think that it could usefully inaugurate the work, it would be improper for me in a presidential address to forecast. Who does it is of less importance than that it should be done, and I cannot but hope that the arguments and instances which I have to-day adduced may help to bring about, not only the doing of the work, but the doing of it quickly.

[The address by Prof. A. B. W. Kennedy to Section G will be found on page 157.]

A NOVELTY IN LAMP SHADES.

Some electrical firms are introducing striking and pleasing novelties in electric lamp and candle shades, some of which are on view in the showrooms of the Edison and Swan Company, Messrs. Rashleigh Phipps and Co., Mr. Frank Suter, etc. The shades are made of a specially selected description of natural feathers, dyed in choice shades, and arranged in artistic shapes and combinations of colour. Among these may be cited some beautiful designs of shades for floor and table lamps, consisting of various kinds of flowers made separately and grouped together on skeleton frames. The effect obtained is quite different from the somewhat hackneyed style of silk and lace shades that are now much in vogue. The general construction of these shades is protected by patent, and every design is registered. They have mainly been designed by Miss Beatrice Davenport for the Plume Company, for whom Messrs. Chas. Ingle and Co., of 157, High Holborn, are the wholesale agents.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE MARQUIS OF SALISBURY AT THE B.A.

It is well that from time to time the president of the British Association should be someone not generally understood to be steeped to the lips in scientific lore, nor a recluse whose home is in the laboratory and whose soft nothings in conversation smack only of life-long scientific studies. Quoting from recollection, was it not Burns who said:

> "O wad some power the giftie gie us
> To see oursels as ithers see us"?

And so one outside the charmed circle of intense scientific thought speaks from that outside, and tells us what he and others think of the scientific progress of the century. Practically, it comes to this, that we have accumulated facts and added largely to knowledge, but the real solution of the great always present problems seems as far off as ever. The Marquis of Salisbury, while not making little of the work done, acts on the scientific body like a good surgeon with a keen knife shredding a limb to save the patient—lays bare the depth of our ignorance, yet leaves us to continue to struggle into the unknown, promising good results, even if the solution of these problems is unattainable. The address of the president of the association does not appeal directly to electricians, except that it shortly, and perhaps incidentally, goes to the root of the structure upon which they and the devotees to optical research base the modern theories. The address is very readable, therefore it is the more unnecessary for us to epitomise it, and can devote more space to the one prominent feature in our portion of science. Light undulation can, according to our theories, only be propagated through some medium. For the want of a more tangible medium the existence of something pervading space was assumed. Its actuality has never been proved, and though this view of the case would be scouted with scorn, there is no valid reason why a second Newton, Young, or Fresnel should not to-morrow propose another theory just as good and just as vulnerable as the one which now holds. Even with the hypothetical ether, which can be and is endowed with any and all the properties required, there is a feeling sometimes finding expression that facts necessitate theories asking too much from it. Lord Salisbury points out its anomalous position, but Section A has more than once heard the despairing cry of "Don't do away with the ether if you leave us blankness." The presidential address puts the whole question into a nutshell. Modern electricians swear by the ether, not because it exists, but because they want it to exist to explain their views. Has not scientific thought always had this tendency? If the theory requires something from the unknown, assume that something, and then assert the correctness of the theory. That theory becomes more or less fashionable for many years, till, in fact, some unorthodox spirit of overwhelming power comes along and suggests a new theory, when his pupils make that theory prominent and cry anathema on all who do not accept it. Lord Salisbury has done good work if by his address he takes a little of the conceit out of the hangers-on of

Digitized by Google

science—those who form the claque, not the real players; for the latter are real seekers after truth, while the former are followers after men. The real scientific man does not assert infallibility—it is only the hanger-on who acts as if he was infallible. The length and breadth, the height and depth of our ignorance of nature are incalculable. A few directions in which it is patent are pointed out in this address, but there are thousands of other problems almost as important and as yet quite unsolvable. Really, instead of being proud of nineteenth-century progress, we ought rather to be deeply humble at the extent of our known ignorance.

TRAIN-LIGHTING.

A note in another column to the effect that the Danish State Railways have been for two years more or less successfully experimenting with the electric lighting of trains, may cause renewed attention to this subject. There can be no two opinions as to the value of this illuminant but the practical difficulties in the way have delayed its adoption. A variety of experiments have been made over English lines, but with one exception little progress can be reported. This being so, the thoughtless man may write down electricity for lighting trains a failure. That conclusion is unsound, for most people can see why an experiment may not succeed, yet why the work on a larger scale would succeed. Few people realise the cost of fitting up for lighting the carriages on a large railway system, and to make electric lighting a success, all, or almost all, the carriages should be fitted for such lighting; otherwise the breaking up of trains mingles the variously-lighted vehicles, and here the difficulty comes in. What manager, or what line, for the matter of that, has pluck enough to sink the initial cost of conversion, say, from oil to electricity? When the train service is such that little or no breaking of trains is involved, the method of lighting is simplified. Oh, but the reader may say, the Danish experiments are with batteries, and most of the other experiments have been similarly made. Granted; and allowing the carriage to be self-contained, we find this difficulty cropping up when trains are broken up: the accumulator-lighted carriages are on different trains, therefore different distances are used through different periods of time, and so the demand upon the accumulators is very varied. This greatly affects the matter of charging; in fact, so troublesome is the matter that most of the experiments have been given up in despair. Two things are wanted to obtain electrically-lighted trains. In the first place, the public using the trains must strenuously kick at the miserable oil lamp now used. It must importune the railway authorities for a better light. Secondly, the railway authorities have still to be educated. Their education seems to go in steps. They take a leap upward and then rest, because the energy expended has exhausted them. They realise only in a fitful way that every departure in ameliorating the travelling troubles of the public has resulted in augmented revenue. The northern and eastern lines have seen this. A better service, better carriages, increased accommodation, each has led to increased revenue, and so it would be if the authorities went further. One day the plunge will be taken, and a big line will go in for electric lighting throughout; then some will agitate for a buffet in every corner and a secluded seat to every individual, but we will be satisfied for the moment with more light. Experiments, to be moderately successful, must be with trains that are not constantly broken up, and should be made with a view rather to court success than failure. Some, we fear, have been made just to see how you could get on under the worst conditions, and here any electrical engineer could easily have predicted failure.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LOWRIE'S INTRAPOSED SYSTEM.

SIR,—Your journal of July 27 contains a description of Mr. W. Lowrie's intraposed automatic system, the main feature of which is an automatic switch. I am afraid the inventor will be disappointed when he actually tries this apparatus. As described, it is not very likely to work satisfactorily. When the switch is off and the current is switched on to the pressure coil, the series coil being short-circuited, a strong current will be induced in the series coil, but this current will not produce equal poles at the pole-pieces. The induction will be due to the combined action of primary and secondary currents, as in any other transformer, and not be in step with either of them. The two pole-pieces will continue to attract each other, and if the resistance of the coils is not high enough to keep the currents within safe limits, a burn-out in one of the coils will be the only result of switching on. If this does not take place, the maximum induction will be somewhat lower than if the series coil was on open circuit due to the drop of volts over the resistance of the pressure coil, but the pole-pieces will at any moment be of opposite polarity and attract each other.

While speaking of automatic alternating switches, I should like to mention a switch of that kind introduced by Messrs. Swinburne and Co. at my suggestion—viz., an automatic synchronising switch to be used instead of the usual synchronising transformer. The controlling electromagnet is a horseshoe magnet, with a coil on each limb and a keeper, which actuates the switch. One of the coils is connected across the omnibus bars of the station, the other across the terminals of the alternator that has to be switched on to the 'bus bars. The keeper will be held up by the electromagnet until the E.M.F. of the alternator is in step with and about equal to the difference of potential between the 'bus bars, then the induction will disappear and the keeper will fall by its own weight and switch the alternator on to the 'bus bars. At the same time it disconnects both coils on the electromagnet, so that no power is wasted except while synchronising. Besides being far more reliable than the ordinary way of synchronising by means of lamps, this switch saves valuable time, because there is no necessity for keeping the alternator at synchronising speed for some time: it is only necessary to speed up fairly slowly; at the moment the synchronism is reached the switch will act, and the alternator is then kept in step in the usual way.—Yours, etc.,

August 7, 1894. S. A. FABER.

Electric Lighting in Ceylon.—Following up the experimental installations in Colombo, an Indian contemporary learns that several hotel proprietors, mill owners, and the harbour authorities intend illuminating their premises with the electric light. Proposals are also before the Municipality for lighting the town of Colombo.

PRACTICAL NOTES ON DYNAMO CALCULATION.* IX.

BY ALFRED E. WIENER.

(*b*) *Radiating Surface of Ring Armatures.*—In ring armatures the construction and mounting of the core may be such that either one, two, three, or all four sides of the cross-section are in contact with the air, but in modern machines, almost without exception, all four, or at least three, of the surfaces constituting the ring are radiating areas, Fig. 20.

In the first-mentioned case (four sides) we have the formula:

$$O_a = 2 \times d_a''' \times \pi \times (l_a + b_a + 4 \times h_a) \quad . \quad (45)$$

and in the latter case (three sides):

$$O_a = d_a'' \times \pi \times (l_a + 2\,h_a) + 2 \times d_a''' \times \pi \times (b_a + 2\,h_a \quad (46)$$

O_a = radiating surface of armature, in square inches;
d_a'' = external diameter of armature, in inches;
d_a''' = mean diameter of armature core, in inches;
l_a = length of armature core, in inches;
b_a = radial depth of armature core, in inches;
h_a = height of winding space, in inches.

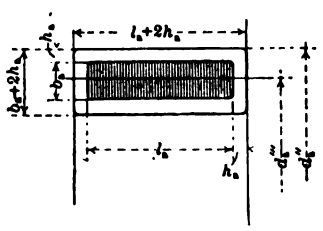

FIG. 20.

18. *Specific Energy Loss—Rise of Armature Temperature.*—While the amount of the consumed energy, W_a, formula (42), determines directly the quantity of heat generated in the armature, the amount of heat liberated from it depends upon the size of its radiating surface, upon its circumferential velocity, and upon the ratio of the pole area to the radiating surface.

The most important of these factors in the heat conduction from an armature naturally is the size of the radiating surface, while the speed and the ratio of polar embrace are of minor influence only; and it is, therefore, the ratio of the energy consumed in the armature to the size of the cooling surface—that is, the specific energy loss—which limits the proportion of heat generated to heat radiated, and which consequently affords a measure for the degree of the temperature increase of the armature.

A. H. and C. E. Timmermann,† of Cornell University, who made the armature radiation the subject of their paper read before the American Institute of Electrical Engineers, in May, 1893, from a series of elaborate experiments drew the following conclusions:

1. An increase of the temperature of the armature causes an increased radiation of heat per degree rise in temperature, but the ratio of increase diminishes as the temperature increases, and an increase of the amount of heat generated in the armature increases the temperature of the armature, but less than proportionately.

2. As the peripheral velocity is increased, the amount of heat liberated per degree rise in temperature is increased, but the rate of increase becomes less with the higher speeds.

3. The effect of the field poles is to prevent the radiation of heat; as the percentage of the polar embrace is increased, the amount of heat radiated per degree rise in temperature becomes less.

Combining these results with the data and tests of various dynamos, the author finds the following values given in Table XXX. of the temperature increase per unit of specific energy loss—that is, for every watt of energy dissipated per square inch of radiating surface—under various conditions of peripheral velocity and polar embrace:

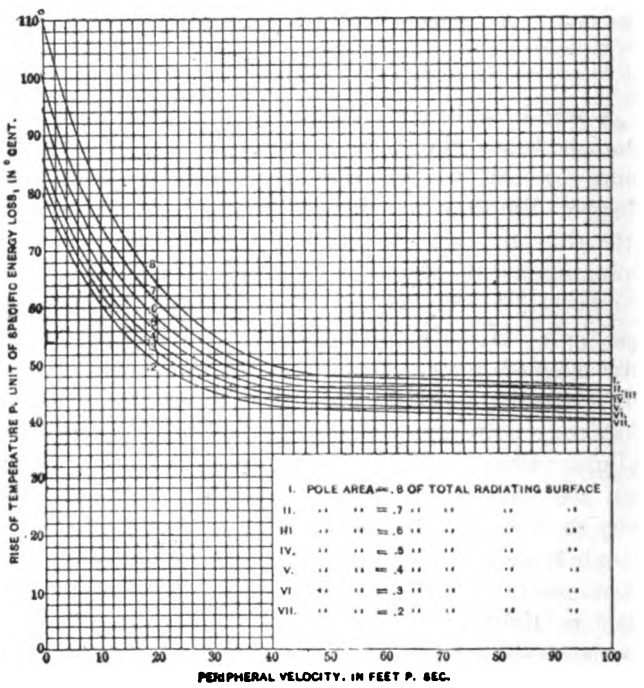
* From the *Electrical World* (New York).

† A. H. and C. E. Timmermann, *Transactions* American Institute of Electrical Engineers, vol. x., p. 336 (1893).

TABLE XXX.—Specific Temperature Increase in Armatures.

Peripheral velocity in feet per second.	Rise of temperature per unit of specific energy loss in degrees centigrade, τ_a. Ratio of pole area to total radiating surface: ·8	·7	·6	·5	·4	·3	·2
0	110	100	95	90	86	83	80
10	80	74	70	67	64	62	60
20	64	61	58	56	54	52	50
30	55	53	51	49½	48	46½	45
40	50	48½	47	46	45	44	43
50	48	47	46	45	44	43	42
75	47	46	45	44	43	42	41
100	46	45	44	43	42	41	40
150	45	44	43	42	41	40	40

In Fig. 21 these temperatures are represented graphically; Curves I., II. . . . . VII., corresponding to columns 2, 3, . . . 8 of Table XXX. respectively.



RISE OF TEMPERATURE P. UNIT OF SPECIFIC ENERGY LOSS, IN °CENT.
PERIPHERAL VELOCITY, IN FEET P. SEC.
I. POLE AREA = .8 OF TOTAL RADIATING SURFACE
II. " " = .7 " " "
III. " " = .6 " " "
IV. " " = .5 " " "
V. " " = .4 " " "
VI. " " = .3 " " "
VII. " " = .2 " " "

FIG. 21.

Multiplying this specific temperature increase by the respective specific energy loss, the rise of temperature in any armature can be found from:

$$t_a = \tau_a \times \frac{W_a}{O_a} \quad . \quad . \quad . \quad . \quad . \quad (47)$$

where t_a = rise of temperature in armature, in degrees centigrade;
τ_a = specific temperature increase, or rise of armature temperature per unit of specific energy loss, from Table XXX. or Fig. 19;
W_a = total energy consumed in armature, in watts, formula (41);
O_a = radiating surface of armature, in square inches, from formulæ (44), (45), or (46) respectively;
$\frac{W_a}{O_a}$ = specific energy loss—*i.e.*, watts energy loss per square inch of radiating surface.

Empirical Formula for Heating of Drum Armatures.—From tests made with drum armatures, Ernst Schulz* derived an empirical formula, which, when translated into our symbols and units, becomes:

$$t_a = \cdot 00045 \times \frac{\mathfrak{B}_a \times P \times N \times M}{O_a} \quad . \quad . \quad (48)$$

t_a = rise of armature temperature, in degrees centigrade;
$\mathfrak{B}_a$ = magnetic density in armature body, in lines per square inch;
P = number of pairs of magnet poles;
N = number of revolutions per minute;
M = mass of iron in armature core, in cubic feet;

* Ernst Schulz, *Elektrotechn. Zeitschr.*, vol. xiv., p. 367 (June 30, 1893), the *Electrical World*, vol. xxii, p. 118 (August 12, 1893).

Digitized by Google

O_a = armature surface, in square inches. (In his calculations, Mr. Schulz, for convenience, takes the external surface of the cylindrical part, $d_a'' \pi \times l_a + \frac{d_a''^2 \times \pi}{2}$, instead of the radiating surface proper, formula (44), but no fault arises from this, as the constant takes care of the difference.)

The numerical factor depends upon the units chosen, upon the ventilation of the armature, upon the quality of the iron, and upon the thickness of the lamination, and consequently varies considerably in different machines. For this reason it is advisable not to use formula (48), except in case of calculating an armature of an existing type for which this constant is known by experiment. In the latter case, Schulz's formula, although not as exact, is even more convenient than the direct equation (47), which necessitates the separate calculation of the energy losses, while (48) contains the factors determining these losses, and therefore will give the result quicker, provided that the numerical factor has been previously determined from similar machines. For various drum armatures experimented upon by Mr. Schulz, the constant varied between ·0003 and ·0005, and averaged about ·00045.

19. *Circumferential Current Density of Armature.*—An excellent check on the heat calculation of the armature, and in most cases all that is really necessary for an examination of its electrical qualities, is the computation of the circumferential current density of the armature. This is the sum of the currents flowing through a number of active armature conductors corresponding to unit length of core periphery, and is found by dividing the total number of amperes all around the armature by the body circumference:

$$J = \frac{K \times \frac{C}{2P}}{d_a \times \pi} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (49)$$

J = circumferential current density in amperes per inch length of core periphery;

K = total number of armature conductors all around periphery;

C = total current generated in armature, in amperes;

2 P = number of electrically parallel armature portions (number of poles);

$\frac{C}{2P}$ = current flowing through each conductor, in amperes;

$K \times \frac{C}{2P}$ = total number of amperes all around armature; this quantity is called "volume of the armature current" by W. B. Esson, and "circumflux of the armature" by Silvanus P. Thompson.

d_a = diameter of armature body in inches; in case of a toothed armature, on account of the considerably greater winding depth, the external diameter, d_a'', is to be taken instead of d_a, in order to bring toothed and smooth armatures to about the same basis; for a similar reason, for an inner-pole dynamo, the mean diameter, d_a''', should be substituted for d_a.

(To be continued.)

BRITISH ASSOCIATION.

Address to the Mechanical Science Section.

BY PROF. A. B. W. KENNEDY, LL.D., F.R.S., M.I.C.E., PRESIDENT OF THE SECTION.

The Critical Side of Mechanical Training.

While there is no place in the kingdom more suitable for a meeting of the British Association than Oxford, and certainly no place in which it is more delightful for the members to meet, it is yet to be admitted that there are few places which have much less in common with the special work of Section G. Nominally devoted to "mechanical science," the section has for many years specially dealt with those branches of applied mechanical science which constitute the business of the engineer—to quote the well-known words of the Royal charter: "the art of directing the great sources of power in nature for the use and convenience of man." The association of this ancient and learned city with boilers and chimneys, with the noise and racket of ordinary mechanical work, seems an incongruity. Even the harmless necessary railway station is kept as far away as possible, and the very river flows with a quiet dignity which seems to shut out the thought of anything more mechanical than the most ancient and futile of water-wheels.

Naturally enough these considerations did not tend to make more easy the choice of a subject for this address, and I have come very near to agreement with a recent critic in the opinion that presidential addresses are, in fact, almost immoral in the nature of things and fit only to be abolished. Finally I decided upon taking up my present subject, as being one in which the academic rather than the technical side of our work comes to the front, while at the same time it does not lead me out of lines in which I have been able, in past years, to work myself. It is now 20 years since I first took any active part in the scientific training of engineers, and five since I ceased to do so. I have often wished that I may have been at all as successful in teaching others at University College as I was, at the same time, in teaching myself. And since I have ceased to teach I seem to have been spending my time in finding out how much better I could now do it than was possible when I was actually engaged in it. This may be pure imagination on my part; there is nothing more easy, as we all know, than to suppose that we know best how to do the things that other people do, and not the things we have to do ourselves. Indeed, I understand that this is the recognised attitude of the really superior critic. If, however, in anything which I have to say, it should seem that I am finding fault with what is now being done, I may at least point out that most of all I am finding fault with myself for not having done right when I had the opportunity—an opportunity which can now never recur. Indeed, instead of the decorous and unobtrusive heading which I have given to this address, I might have indicated its general lines almost as truly if I had entitled it "The Regrets of an Emeritus Professor"—a name which, on a suitable binding, might even have secured it a sale at the railway bookstalls.

I know well—too well—that in the present congested state of the engineering profession there are many of us who do not like to hear the word "training" mentioned at all. It seems to mean merely the preparation of more lads to struggle for a share of work that is even now insufficient to go round. There is no doubt much to be said for this point of view. But against it one must remember that all other professions are equally full, and that, after all, lads must do something. The fault is surely that there are too many lads! If our population is really to go on increasing as rapidly as at present—the benefits of which Sections D, E, and F might have a joint meeting to discuss, if not to discover—it is inevitable that demands should come for more and more complete professional preparation. The man of exceptional parts will come to the front under any conditions, training or no training, in the future as in the past. But for ordinary men—that is, for 99 per cent. of us—it is essential that no advantage should be given to a rival in the fierce competition of life, and for them, therefore, it is of an importance hardly to be exaggerated to obtain the most complete and perfect training possible. At the same time, and on purely general grounds, it can hardly be denied that to raise the standard of our profession is indirectly to confer a benefit on the whole community. I hope, therefore, that in making certain suggestions about the training of engineers, it will not be thought that I am desirous of increasing their number, which is really an end as far as possible from my own wishes. Whether the number increases or stands still or falls off, it is of importance from every point of view that those who come forward should be as well prepared as possible. And even the most conservative of us are compelled to recognise that the standard required in engineers' offices now is enormously higher than it was 30 years ago. This may truly be either the cause or the effects of improved training, but in either case it has made the training itself a necessity.

The particular aspect of mechanical training of which I wish to speak is its critical side. I do not know how a man should be trained to be an inventor. I would not tell anyone if I did! To be a creator in mechanical matters—which, however, is a quite different thing—is a faculty given only to a very few, and with them it is "born, not made." Many of us, however, without being either inventors or creators, have sufficient natural aptitude or inclination towards things mechanical to form a basis for the trainer or educator to work on, with some hope that he may be of service. About the sciences which should be taught to such men, or the methods of teaching them, about the extent and nature of their experience in shops or on works, I do not intend to speak. I shall confine myself to one aspect of the training only, an aspect which is perhaps not always sufficiently clearly kept in view—the aspect which I have just called the critical side of mechanical training. An

Digitized by Google

engineer is a man who is continually being called upon to make up his mind. It may be only as to the size of a bolt; it may be as to the type of a Forth Bridge; it may be as to the method of lighting a city; or only as to the details of a fire-grate. But, whatever it is, once it is settled it is decided irrevocably—it is translated into steel and iron and copper, and cannot be revoked by an Act passed in another session. The time given him in which to decide may be a day, or a month, or a year, but in any and every case (so far as my own experience goes) it is about one-tenth part of the time which he would like to have. It is only in rare cases that the decision is obvious—most often there are more courses open than even the most facile politician ever dreamt of. The matters are too complex to be dealt with mathematically or even physically; even if they were not, there are few engineers who would have the special capacity to handle them. Moreover, their solutions are seldom "unique." From this point of view, the whole use of college training, of workshop practice, of practical experience, is to provide the engineer later on with the means of critically examining each question as it comes up, of reviewing systematically the *pros* and *cons.* of each method of dealing with it, of coming finally, rapidly, and positively to some defensible decision, which may then be irrevocably carried out.

In the case of a problem in pure mathematics or physics, where only one right solution can exist, that solution is arrived at by the help of a thorough knowledge of the science in question; there is little room for the critical faculty except as to method; the result is either right or wrong. With our work, on the other hand, solutions of all problems except the very simplest—in other words, decisions on all points which present themselves—can be arrived at only by a process of criticism applied to the problems, to their statement, to their condition, to all their many possible solutions. The development of the necessary critical faculty should be one of the chief aims of every teacher and every student. A scientific training cannot make a man an engineer. Perhaps it is impossible for anything to make a man an engineer unless he has grown that way from the beginning. But a scientific training may make him, or at least give him the possibility of making himself, a critic.

In the vigorous attempts which have been made to specialise the education of engineers very early, I am afraid that the idea of teaching subjects is sometimes too prominent, to the neglect of matters less obviously useful. It is, of course, one thing to know a subject from the examination point of view, and quite another to be able to think about it, and still another to be able to write about it. In particular, I have often regretted to find how little attention has been given to a matter which perhaps may be called literary rather than scientific, but which is all-important in criticism—I mean to the power of expression. It is not easy to overrate the importance to the engineer, as to other folk, of the power of saying clearly what he means, and of saying just what he means. I do not mean only of doing this for its own sake, but because if a man cannot say or write clearly what he means, it is improbable that he can think clearly. By the power of expression I do not mean, of course, the mere power of speaking fluently in public, a thing which appears physically impossible to some people. I mean rather the power of expression in writing, which carries with it clearness and consecutiveness of thought. It is difficult to know how this matter can be taught, but at least it can be insisted upon probably to a much greater extent than is commonly the case. A man requires to see clearly not only the exact thing which he wants to say, but the whole environment of that thing as it appears to him. Not only this, but he must see the whole environment of the same thing as it appears to the persons for whom he is writing, or to whom he is speaking. He has to see what they know about the matter, what they think, and what they think they know, and if he wishes to be really understood has got to do much more than merely write the thing he means. He has carefully to unwrite, if I may use the expression, the various things that other people will be certain to think that he means. For, after all, the great majority of people are very careless listeners and readers, and it is not for the small minority who are really exact in these matters that one has to write. Moreover, it is a great help to clearness of thought and expression to keep before one always an ideal audience of people who will certainly misunderstand every single sentence about which any misunderstanding is in any way possible, and some others as well.

In attempting to think out or to discuss any question, whether it be technical or non-technical, in fact, as long only as it is non-political, the first necessity is probably a knowledge of the question itself, and not only this, but also a proper understanding of its whole environment. This knowledge must be of such a kind as to distinguish what parts of it are important, what parts of it are unimportant, what parts can be described in two sentences, and what others may require as many paragraphs; what parts affect the result but little, however large they seem; and which ones must be considered vital, although their very existence is difficult to discover. The faculty which enables a man to handle his knowledge in this fashion may be summed up in the single expression "sense of proportion." Moreover, the knowledge, to be of real value, must be as totally free from prejudices and prepossessions as in the most rigorous branch of pure science, and as thoroughly imbued with a healthy spirit of scepticism. One is accustomed to think of engineering work as mainly constructive; but, after all, it is quite as much critical. In almost every department of mechanical work there are half-a-dozen ways of solving any particular problem. In some fashion or other the engineer must be able to judge between these various methods—methods which are often very much alike, but each of which may possess certain particular advantages and certain particular drawbacks. The arithmetical criticism which merely counts the advantages and the drawbacks, and puts an equal number of the one against an equal number of the other, is common enough, but obviously useless. The very first necessity to the critic is that he should have what I have just called the sense of proportion—a sense which will enable him to distinguish mere academical objections from serious practical difficulties—which shall enable him to balance twenty advantages which can be enumerated on paper by one serious drawback which will exist in fact—which will enable him, in fact, to place molehills of experience against mountains of talk. It is perhaps a doubtful point how far this sense of proportion can be taught at all. No doubt it can only be built up upon some natural basis. I am sure that in engineering we all know men whose judgment as to whether it was advisable to take a particular course we would accept implicitly, because we know that it is based on large general criticism, in spite of the most elaborate and specious arguments against it set down on paper. Any third-year student—not to go still further back—can criticise perfectly along certain very narrow lines, just as anyone can learn the rules of harmony, and can write something in accordance with them which purports to be music. But, after all, the music may be music only in name, and the criticism may not be worth the paper it is written upon, however formal it may appear to be, unless the writer is thoroughly imbued with a sense of the proportionate value of the different points which he makes. To take the commonest possible case, I dare say we have all of us heard certain methods, mechanical, chemical, or other, stigmatised as totally wrong and absolutely useless because they contain certain easily provable errors. I am sure, too, that most of us could give illustrations of cases in which this has been said with the very greatest dogmatism when the errors of the impugned method are not one-tenth part as great as the equally unavoidable errors of observation in the most perfect method.

Probably the best special education in proportion which a man can have is a course of quantitative experimental work. I say quantitative with emphasis, as meaning something much more than mere qualitative work. Here, I think, comes in the usefulness of the engineering laboratory. We require that the training should be not only in absolute measurement, but in relative measurement, the latter being quite as important as the former. Many kinds of measurements stand more or less upon a level as a training of the faculties of observation in themselves, but no single kind of measurement is sufficient as a training in proportion. A year spent in calibrating thermometers or galvanometers might make an exceedingly accurate observer in a particular line, but it would not give the observer a knowledge of what even constituted accuracy in other directions; for accuracy is a relative and not an absolute term. In most engineering matters the conditions are, unfortunately, of a most complex kind—so complex that our problems are incapable of any solution sufficiently exact to satisfy the mathematician or physicist. The temptation to treat these problems as the mathematician treats those with which he deals—namely, to alter the assumed conditions in order to get an exact solution—is a very strong one. I am afraid it is most strong often in those engineers who are the best mathematicians. It is a temptation, however, steadily to be resisted. We must assume our conditions to be what they actually are, and not what we should like them to be; and if we cannot obtain an exact solution of our problem with its actual conditions, so much the worse for us, not so much the worse for the conditions. Our first duty is generally to find out the conditions; if they are disadvantageous (in fact I mean, and not merely in the problem) to alter them if they can be altered, but not to ignore them because they are inconvenient. We have then to find out the extent to which the known conditions permit any exactness of solution at all, and, finally, we have to keep this in view as a measurement of the highest accuracy which is attainable. To work out certain branches of the problem with such minuteness as to give us apparently very much greater accuracy than this is not only useless, but is apt to be positively misleading, as giving an impression of an accuracy which has no real existence. The relative value of accuracy in different sets of observations is in itself a matter in which a sense of proportion is wanted, and often very badly wanted. Where one has to measure half-a-dozen things, of which two are very easily measured, and the remaining four are only measurable with great difficulty, it is only human nature that we should spend our energies on getting extremely accurate results with the first two and roughly do our best with the others. It is very difficult

Digitized by Google

under such circumstances to remember that the accuracy of the whole is not the accuracy of the best part of our work, but of the worst.

The extraordinary effect of a want of sense of proportion is nowhere better shown than in the absurd statements which are constantly made as to technical matters in public prospectuses, and the still more absurd statements made in those very numerous documents of a similar kind, of which some of us see a great many, but which do not finally emerge into public view. Fortunes are apparently to be made by inventions which, although doubtless ingenious, yet only concern one way of doing a thing which could be done equally well in half-a-dozen other ways. Everyone is expected to run after a piece of apparatus which is to save 50 per cent. of something, the total cost of that something, however, being so very small that nobody cares to save in it at all. I need hardly mention the all too-common case where a contemplated saving of 10 per cent. in the cost of a material works out yearly to an amount much more than equal to the whole cost of the original article. I believe that experimental work in an engineering laboratory can educate this critical sense of proportion very admirably in a number of ways. In the first place, it directs quantitative work into very varied channels, and not along one particular line. Secondly, it compels the observer to combine a number of measurements in such a way that the relative importance of accuracy in each can be seen. In the case of an engine trial, for instance, the combined results are affected by the accuracy of measurements of the dimensions of the machine, by the apparatus and methods used for measuring the water, by the indicator and by its springs, by the speed counter, by the thermometers, and so on. An error of 1 per cent. in counting the revolutions is just as important as an error of 1 per cent. in measuring the water, or in measuring the mean pressure. I am afraid that one could point to a good many cases in which this has been more or less forgotten. Then, by making a series of measurements all in absolute quantities, the relative importance of each quantity to the desired total result can be seen. Thus it will be found that changes in certain quantities affect the total result to a very small extent, while changes in others affect it very largely, so that not only is the accuracy with which different quantities can be determined very different, but also the same degree of accuracy is of very different importance according to the particular quantity to which it refers. Once it is found that a final result is exceedingly little affected by a particular set of changes, it ceases to be of importance to measure or observe those changes in any extremely minute way, and of course the reverse holds equally good. Finally, and this, perhaps, is the most important matter of all, measurements in such a laboratory are made to a great extent under the complicated conditions under which the actual final result has to be obtained in practical work. They are not made under the conditions which insure the greatest individual accuracy of each result.

It will be seen that throughout, but particularly in the two last points which I have mentioned, the work of an engineering laboratory is in intention and in essence different from that of a physical laboratory. The aim of the latter is to make its problems as simple as possible, to eliminate all disturbing elements or influences, and to obtain finally a result which possesses the highest degree of absolute accuracy. In most physical investigations the result aimed at is one in which practically absolute accuracy is attainable, although attainable only if infinite pains be taken to get it. It is the business of the physicist to control and modify his conditions, and to use only those which permit of the desired degree of accuracy being reached. In such investigations it sometimes becomes almost immoral to think of one condition as less important than another. Every disturbing condition must be either eliminated or completely allowed for. That method of making the experiment is the best which ensures the greatest possible accuracy in every part of the result. The business of the engineer, on the other hand, is to deal with physical problems under conditions which he can only very partially control, and the conditions are a part of his problem. He does not, for instance, experiment with a steam-engine so made that it can work with a Carnot cycle. It is in the nature of the case that he must experiment with a much less perfect machine. In burning fuel he does not use apparatus specially made to absorb the whole heat of combustion, but in the nature of the case has to investigate the behaviour of apparatus in which a very large part of that heat is unavoidably wasted. So one might go on through an immense number of instances. Perhaps the whole matter may best be summed up by saying that in a physical laboratory the conditions of each experiment are under the control of the experimenter, and are subservient to the experiment itself. In an engineering laboratory the conditions form part of the experiment. However much more difficult or complicated they render it, they still unavoidably form part of it—an experiment under any other conditions, or with those conditions removed, would *ipso facto* be irrelevant.

A critical training in matters mechanical is, however, only too similar to the celebrated training of the Mississippi pilot which so nearly broke the heart of Mr. Mark Twain. Whenever the whole matter seems to be completely mastered from one point of view, it is only to find, with a little more experience, that from another point of view everything looks different, and the whole critique has to be started afresh. Machines cannot be finally criticised—that is to say, they cannot be pronounced good or bad—simply from results measurable in a laboratory. One wishes to use steam plant, for instance, by which as little coal shall be burnt as possible. But clearly it would be worth while to waste a certain amount of coal if a less economical machine would allow a larger saving in the cost of repairs. Or it might be worth while to use a machine in which a certain amount of extra power was obviously employed, if only by means of such a machine the cost of attendance could be measurably reduced. In fact, what may be summed up in the phrase the "worth-whileness" of economies, is in itself a matter on which a whole paper might be written. Unfortunately, the latter points which I have mentioned are just such as cannot easily be measured in laboratory work, or, indeed, in any other way whatever, except by actually using the apparatus in question. All that can be said is that a careful training in the critical measurement of comparatively simple points fits a man more than anything else to gauge accurately the importance of such other matters as I have mentioned. No doubt there are many men in whom the critical faculty is insufficiently developed to allow them ever to be of use in these matters, but to those who are intellectually capable of the "higher criticism" it must be, I think, of inestimable benefit to have had a systematic training in the lower.

Is there, then, any general standpoint from which mechanical criticism can be directed? Certain points are obvious, but probably the whole matter cannot easily be generalised. A city has to be supplied with water; there are three requisites: that the water should be of proper quality, of sufficient quantity, and that it should be brought in at a reasonable cost. But in such a case the first two are so enormously more important than the third, that the ideal is comparatively simple (of course, this is quite a different thing from being simply reached). A city has to be supplied with electric light: the essential conditions are similar. But in this case there are so many qualities which are equally proper, and there are so many different ways of bringing it in in sufficient quantity, that the third point—namely, the cost—becomes especially important. A factory has to be driven by steam power: the amount of power that is wanted can be produced by so many different types of engine and boiler—all capable of approximately equal economy, and all claiming equal freedom from breakdowns—that the choice is a peculiarly difficult one from the critical point of view. It seems almost impossible that a criticism on any one basis could meet all the three cases which I have supposed, unless that basis were that the thing supplied should be the absolutely fittest, having regard to all the conditions of each case and the relative importance of each condition. Possibly in all cases we could get at some generalisation which would show us which was the absolutely fittest, if only the necessary data were in any way complete, which they very seldom are. Perhaps in one sentence we may say that that scheme, or system, or machine, will be the absolutely best in any particular case which will the longest survive and maintain its place in its particular environment. I cannot doubt that this development of Darwinian ideas in the world of the inorganic is a legitimate one. Of course the problem would be comparatively easy in each particular case if only the environment would stand still. It would even be comparatively easy if we knew how the environment was going to alter, but this we are unable to do. We only know that it certainly will change and will go on changing, and that therefore the things which we make now have not got to survive in the conditions in which we make them, but have got to survive through some new sets of conditions of which we know nothing. I do not think the difficulty is in any way met by the popular method of guessing at what will be wanted 50 years hence, which generally means simply guessing at something very big. It is of no use making our ships or our engines of a type which we choose to imagine will be that of 50 years hence. If we do they will be of no use to-day, and for that very reason they will not even be in existence, useful or other, at the end of the 50 years. Sufficiently sad illustrations of this will occur to everyone in very different directions. I hope I shall not be considered churlish in saying that I do not think that the men who have worked on this principle have really been farseeing, or have really brought us much forward. They have been men often of genius, often of great personal fascination, always of immense imagination. But they have proceeded by methods essentially opposed to anything like the gradual evolution which must occur in technical as it does in natural matters, and in too many cases the results of their labours have not even been giants, but only monsters.

As to what causes one thing to survive rather than another we can only speak very generally. Mere survival may come about by the accident of a peculiarly tough constitution. A few engines built in the times of James Watt are still to be found at work in our own day, but can no more be taken as the fittest type than some solitary megatherium would be who,

Digitized by Google

having outlived all his contemporaries, was able in after ages to look down upon his pigmy and short-lived successors. Mere length of life in such a case may be a mere accident, and is not itself a proof of fitness. We have it thrown at us every now and then that our engines nowadays do not last like the old ones, as if the mere existence of a very old machine were a proof of its virtues. It is certainly a proof of the excellence of its construction—or, as one may say, of its constitution—and perhaps also of the very small amount of work it has done in proportion to its life and its dimensions. It is sometimes, I am afraid, rather humiliating to have to remember that, to a very great extent, the question of the fittest, so far as it affects us, is a financial one. In manufacturing processes efficiency and economy tend to survival because they lead to decreased cost of production. In structures or other large permanent works those types tend to perpetuate themselves which require the least material—that is, in which the material used is disposed to the best advantage—and in which the outlay on labour is also smallest, assuming, of course, equal fitness in other respects. There is, no doubt, at present a tendency to dispute this altogether, and to treat all reductions in cost of labour as disadvantageous, unless, indeed, the labour be very highly skilled, in which case its remuneration must necessarily be brought down for the sake of equality! I imagine this tendency will last exactly as long as the faithful can get some other people to pay the increased cost, and will thereafter determine itself somewhat suddenly. It can no more stand in the way of natural progress in engineering matters than could the somewhat similar outcry against the introduction of machinery into manufactures two generations ago. It would be as wise to paint a generation of cats green in the hope of compelling natural selection to work along new lines.

I think we may fairly assume, therefore, that efficiency and economy are both legitimate criteria as to ultimate fitness, and will remain so. Moreover, they are both matters in which measurements can be made, and as to which judgment can be guided by such measurements. But there are other characteristics, not directly measurable, by which we can in some degree form an opinion as to the ultimate fitness of things or processes.

One set of considerations which has great critical importance is summed up in the word simplicity. This does not mean fewness of parts. Reuleaux showed long ago that with machines there was in every case a practical minimum number of parts, any reduction below which was accompanied by serious practical drawbacks. Nor is real simplicity incompatible with considerable apparent complexity. The purpose of machines is becoming continually more complex, and simplicity must not be looked at as absolute, but only in its relation to a particular purpose. There are many very complex-looking pieces of apparatus in existence which work actually so directly along each of their many branch lines as to be in reality simple. I believe it almost always happens that the first attempt to carry out by a machine a new purpose is a very complicated one. It is only by the closest possible examination of the problem, the getting at its very essence, that the machine can be simplified, and this is a late and not an early stage of design. If a mechanical problem is really only soluble by exceedingly complicated apparatus, it generally becomes a question whether the solution is worth having. There is no impossibility in making a machine that will do anything. But the very simplest possible form of apparatus which would wash our hands for us in a suitable manner is probably so very complicated that for many years to come at least that operation will be performed by manual labour. Very closely allied to simplicity is what I may call directness. In nearly all mechanical processes certain transformations are unavoidable. In many mechanical processes, as I have recently had occasion to mention, a very large number of transformations is at present practically unavoidable. I myself cannot help thinking that probably one of the most distinct signs of fitness is a reduced number of transformations, the bringing of the final and the initial stages as close together as possible, and cutting out altogether the apparently worthless middle processes. But any generalisation of this kind must be very cautiously handled; these apparently useless processes are no doubt in certain cases as indispensable as is the much abused middleman in matters economic. In a critical view of any case where similar results are aimed at by hand-work and by mechanical means, it is important to recognise that the similarity of result should very seldom become identity. In the first machine to do anything mechanically which has before been done by hand, the error is often made of trying to imitate the hand-work rigorously. The first sewing machines were, I believe, made to stitch in the same way as a seamstress. It was not until a form of stitch suitable for a machine, although unsuitable for hand, was devised that the sewing machine proved successful as a practical matter. In another but analogous line, too, you may remember that the first railway carriages were practically stage coaches put upon trucks, from which the present carriages have only very slowly been evolved. The critic has also to remember that very often the attainment of some very unimportant point, or point of which the importance has been greatly exaggerated, is made the reason mechanically for very great complication. The question of proportion comes in here again, and it has to be considered in any particular case whether the academically perfect machine, which is also extremely complicated, is not inferior to the almost equally good machine which has been constructed in a practicable shape—it almost always is so.

I have endeavoured in my remarks to indicate what appears to me to be the attitude of the engineer towards a very large portion of the work which comes into his hands. In order to deal with the work it is necessary for him first of all to have a certain definite knowledge of "things"—that is to say, both of the various subjects which form part of the curricula of all technical schools, and of the further matters which form as it were his professional alphabet. These last he learns not from books or lectures as a student, but by example and attempt, as does an artist. Of this part of his training I have said nothing; it has been perhaps sufficiently talked about of late years, and there is little to say which I could have made interesting to a general gathering like this. I cannot leave it altogether, however, without dealing with one matter. Exceptional men are all-round mathematicians or physicists, still more exceptional men are both; but for ordinary folk the study of one side of mathematics, or of a single branch of physics, is the work of a lifetime. The engineer is bound to know his own profession, by hypothesis, and it is in itself no small matter. Yet in addition he must know some mathematics, some physics, some chemistry, even also some geology, if he is to take any high rank in it. It is, therefore, surely in the very nature of things impossible that he should be a great mathematician or a great physicist, or should devote as much study to those most fascinating sciences as if they themselves were the work of his life. Therefore I beseech my friends of Section A to do what they can to modify their natural attitude of superiority—even of contempt—towards us, especially when we are students. The young engineer—I speak as a member of the great majority of the ordinary kind—would probably never have chosen his profession if he had had special aptitude for mathematical work. Having chosen it, he has to look at mathematics simply as a tool, a means to an end, not an end in itself. I cannot myself see that this point of view is one disrespectful to the parent of all the sciences, and I am confirmed by the knowledge that one or two of the greatest mathematicians in the country are of the same opinion and have the courage to act on it—with infinitely beneficial results to the young men they have to deal with. But I know that to mathematicians in general—the physicists are not so bad—the very name of engineering student is odious, indicating only a man who wilfully refuses to make mathematics his "first subject," and who therefore deserves neither consideration nor quarter, to whom it is privilege sufficient that he should be allowed to pick up such crumbs as he can digest from a table prepared for his betters. I humbly protest that we deserve better treatment. It is no doubt a great misfortune to us that we cannot afford to spend our training time preparing for examinations, and that we have been compelled to choose for our future a career in which mathematics plays only a secondary part. It is our further misfortune that we have to solve 20 real live problems, each demanding a real live answer, for every single one which otherwise we would have worked out on paper. Perhaps it is also our misfortune—or it may be only our thickheadedness—to believe that in consequence of this we are quite able to judge for ourselves what units it is most convenient for us to work in, what nomenclature satisfies our requirements, and that we are as capable of getting our "g's" in their right places as even some of our distinguished critics. But this is the end of the nineteenth century: philanthropy fills our breasts. May not our misfortunes call out some pity, and not alone contempt? In spite of solemn warnings which I have lately received in the Press against the monstrous idea that a presidential address should contain any individual opinions, I venture to repeat here what I had lately an opportunity of saying before a Royal Commission—that in cases where a university or university college takes in hand the preparation of engineers—and I hope that such cases will grow in number—they should provide for them special training in mathematics, and probably also in physics, distinct from the general training in these subjects most suitable for degrees. I say this with the full knowledge that I may be accused of wishing to degrade the purity of scientific work, and at the same time with the full knowledge that I have no such wish. On the contrary, this special training is the only means by which the rank and file of us will ever know any mathematics at all. And I can say from my own knowledge that if only we can be made what I may call mathematically articulate beings, we shall be able to repay the kindness by placing before the man of pure science problem after problem of transcendent difficulty, of immense interest, and having no single drawback whatever except that its solution may really be "useful"; and, after all, this need not be brought too prominently under his notice.

This digression has turned out a long one. I have only further to say that my main object in this address has been to indicate,

Digitized by Google

as well as I could, the general attitude which the engineer must of necessity take up towards much of his work—the point of view from which he must look at it. I shall be extremely glad if anything which I have said should cause this attitude—this point of view—to be more clearly kept in mind in the period of training than probably has been hitherto the case.

SOME REMINISCENCES OF STEAM LOCOMOTION ON COMMON ROADS.*

BY SIR FREDERICK BRAMWELL.

It has occurred to me that this paper may have some interest for Section G on two grounds: (1) that it deals with a branch of mechanical engineering of which the present generation knows practically but little; and (2) that it involves very largely the subject of water-tube boilers or their equivalents. I intend to confine myself to some reminiscences on this subject, embraced, so far as my own knowledge goes, between, say, six or seven years in the thirties or forties of this century. I think I am right in saying that by about 1825 our turnpike roads, and the stage coaches which ran upon them, had attained to the highest degree of excellence. At this time passenger railways were practically "in the air," omnibuses were running in London, and cabs were superseding the old hackney coaches; and there was a general feeling that on our magnificent turnpike roads increase of speed and economy could be attained by the employment of the steam-engine, and it was also felt that such a mode of propulsion would compete successfully with the omnibuses. The natural result was that very many men, more or less ingenious, and more or less practical, devoted their attention to the subject of steam locomotion on common roads.

I propose to describe briefly some few among the whole number of those inventions which really resulted in carriages that did practical running on common roads Certainly the most enduring and successful of these men was Walter Hancock. He took great notice of me, then an apprentice, and, after his day's run in London, frequently took me down on the coach to his factory at Stratford. I became very much interested in this subject and took occasion to see all that was to be seen, and to hear all that there was to be heard. Another coach that did good service was that of Summers and Ogle. Summers was son-in-law to the engineer, Hague, to whom I was apprenticed. I was thus, as it were, in a steam-locomotion-on-common-roads atmosphere. In 1830, as you all know, the Manchester and Liverpool Railway, which I think I may fairly call the first real passenger railway, was put to work. Nevertheless, in 1831, a Parliamentary Committee of the House of Commons was constituted, which committee reported in 1832, and I think it only fair to the enterprise of steam carriages on common roads to give the summary of their report. You will see that they refer to the excessive tolls that have been imposed, and state that such tolls would be prohibitory, if they were to remain unaltered. But not only did the opponents of steam carriages on common roads oppose them by obtaining heavy tolls to be laid on, but they used actual physical obstruction. But I do not think that either excessive tolls or road obstructions were the real cause of the cessation of the steam carriage enterprise upon common roads Year by year railways were increasing, and the public lost interest in the common road steam carriage, which was merely to develop a speed of some 15 miles an hour, which required a large expenditure of power for the weight moved; and they turned, and wisely turned, towards the iron way.

Among the six or seven names with which I am most familiar it is difficult to assign any definite order of sequence of invention, inasmuch as in some cases the same inventor took out patents at varying dates. Hancock had a patent in 1827; so had Gurney; Summers and Ogle, in 1830; Church, in 1832; Macerone, 1833; Dance, 1833; and Hancock another patent as late as 1839. Hancock, and most of those who worked on the subject, dealt very wisely in one most important respect with their carriages to be used on common roads—that is to say, the vehicles themselves were very commonly like a large stage coach, or (as I shall have to say with respect to Hancock) were of the omnibus form, or deviated from this by the adoption of the *char-a-banc* construction. With the exception of the driving wheels there was no moving part of the machinery visible. There was no noise from the exhaust (in the best of them) nor any visible indication of fire or steam—that is to say, neither smoke nor a white cloud. Their appearance, therefore, was not such as to be of necessity alarming to horses. But for years after Hancock steam locomotion on common roads remained in abeyance, and when it was taken up again it was with the totally different object of traction engines, travelling ploughing-engines, and road-rollers. These were carried out by some of the best of our mechanical engineers, and as machines were excellent; but with respect to the horse difficulty were about as bad as they well could be. All the moving machinery was visible; there was the "barking" noise due to the steam blast, they occasionally emitted fire, and their general forms must have been an abhorrence to any horse possessed of the slightest particle of good taste. The result, as we know, has been legislation confining the use of these vehicles to night, or, if worked in the day, to be preceded by a man with a red flag and various paraphernalia.

I will now give a few particulars of the steam carriages to which I have already alluded, and I will commence with that of Hancock. In all cases the passengers and the engine and boiler were carried on one and the same structure, except when, to show the power of the engine, an ordinary omnibus body was towed behind the steam carriage. Whatever may have been the nature of Hancock's earlier experiments, he settled down into a construction of boiler consisting of a number of flat chambers placed side by side, with spaces for the ascent of the products of combustion in between the chambers containing the water. The boiler was an equivalent for a water-tube boiler, in that (as in water-tube boilers) the fire was outside the water, and not inside. This boiler combined lightness, strength, and large heating surface. By a simple arrangement there was formed a complete connection for the water at the lower part of all the chambers, and another similar connection for the steam at the upper part of the chambers. Into one of the lower sockets was pumped the feed water, and on the upper sockets were placed the safety-valves. The steam to the engine was taken off by a pipe from a central intermediate ring. The upper and lower sockets were also connected by a vertical pipe, external to the fire casing, in which were placed at frequent intervals a series of—not gauge cocks, but—gauge valves to serve the purpose of a glass water gauge. It should have been stated that the joints between the various chambers were made by a simple copper-wire ring, somewhat flattened out by the pressure produced by the nuts of the tie-bolts. For years past such or similar modes of making joints tight have been well known, but Hancock was the first, or certainly among the first, to dispense with red lead and other abominations, and to make metal to-metal tight joints. I do not remember how he made his steam and water connections. I am not sure, but I believe, that this boiler was put into a steam carriage, which however, was a failure Hancock's collection of chambers was placed a short distance above the fire, or in the last patent was placed not directly over the fire, but at the side. There was an external casing which contained the boiler, the fire-chamber, and the ashpan. This pan was closed and the draught was excited by a fan driven off the main engine The waste steam was blown into the ashpit and passed up through the fire, with the result that, except upon a very damp morning, at first starting there was not, as I have already said, any visibility of the waste steam, neither was there any sound. The safety-valve also, when it blew off, delivered the escaping steam into a silencing box. The engines were of the inverted vertical type, working on to a crankshaft, carrying a pitched pulley for a chain. This pulley could be uncoupled from the shaft by a clutch, and then the engines could be worked to drive the fan to get up steam or to feed the boiler. I need hardly say this was long before the days of injectors, and was also long before any common use of donkey engines. On the axle of the hind wheels was a corresponding pitched pulley, either of equal diameter with that on the crank-shaft, or, I am inclined to think, of somewhat greater diameter. The wheels were of wood, having very strong spokes, enclosed in a cast-iron nave, with covering plate. They were loose upon the ends of their shaft, and had, on the outsides of the nave, two driving projections. On the ends of the shaft were two drivers, which could be drawn out of gear with the wheels by screws. In ordinary running, both drivers were in gear, but there was left a very large amount—probably 100deg. or more—of that which may be called "back-lash." Supposing that in steering through the streets it became necessary to make a slight curve. The result was that the wheel on the inner side of the curve did the driving, while the wheel on the outer side overran the driver. It thus became possible to follow a sinuous track with great ease so long as the curves were inconsiderable in length. This preparation to accommodate the driving wheels to the conditions needed when making a curved track would, in these days, be, of course, wholly unnecessary, on account of the employment of the "jack-in-the-box" arrangement, to attain the desired end, and to do so in a much better way. In the latest of Hancock's coaches, the "Automaton," provision was made for partially condensing the exhaust steam by passing it through condensers of somewhat the same construction as that of the boilers, and placed in the water-tanks which were under the floor of the *char-a-banc*. I am under the impression, however, that these were never a success.

In these days injectors were not, and considerable difficulty had from time to time been experienced by the sticking up of the valves of the feed pumps. To guard against this, Hancock used two suction valves in succession and two delivery valves in succession The steering was done by means of an ordinary fore-carriage fixed upon a central vertical pin, carrying a pitched chain-wheel geared up to a wheel of the same kind keyed on to a vertical steering spindle, on which was a hand-wheel It was found in the outset, especially when going over pavement, that the blows inflicted by the pavement on the forewheels were communicated to the arms of the steersman with a very distressing effect. This was entirely got over by the simple expedient of a foot-brake These coaches worked for a period extending over 12 years. They, or some of them, made long journeys with great success; but their most interesting use, as showing the ability of steam-driven coaches to cope with the needs of the traffic of a great city, of many road materials, and of gradients exceeding that of any hill on the road from London to Holyhead, was their lengthened employment for ordinary omnibus traffic between the Bank and Paddington, and, morning and evening, between the Bank and Stratford.

The next carriage with which I will deal is that of Goldsworthy Gurney. The boiler was essentially a water-tube boiler, and consisted of two main tubes (cast iron I believe they were) placed horizontally parallel the one above the other; from the lower of these main tubes there issued a series of wrought-iron tubes slanting upwards for some distance, and then bending, continuing on,

* Abstract of a paper read before Section G of the British Association.

Digitized by Google

over, and to the top main tube. This carriage (or rather these carriages) made various experimental runs with more or less success—notably one from London to Bath, and worked for a considerable time between Cheltenham and Gloucester—but was eventually abandoned. I never saw it running, nor did I ever see it together as a whole; my personal knowledge was confined to the boiler, and was of the character of that of the converted cannibal, who, being asked what he thought of the late bishop said he knew he was a very nice man for he had eaten a bit of him. The very first day of my apprenticeship was occupied in holding the chisel rod for a labourer who was cutting up the boiler into scrap.

The next carriage I will mention was that of Sir Charles Dance. This was a steam traction engine, and had no seats for passengers, but towed an omnibus behind it. The engine was built by Messrs. Maudsley and Field. The boiler is a strictly water-tube boiler, and in cross-section somewhat like a capital letter X. Smaller tubes started from horizontal tubes at an angle of 45deg. or thereabouts, interspaced so as to pass each other at the centre of the X, and going upwards until they reached the special arrangements by which the steam was separated from the water. The pipes continued upwards, and were united by cross tubes from which the steam was taken. This carriage worked extremely well, and went at a very considerable pace. For instance, I remember travelling by it from London to Reading—a distance of about 45 miles—which, on the down journey, was performed from Hyde Park Corner in 3¼ hours, towing a full omnibus behind it. I remember we put up in the inn yard of a coaching house—the name of which I have forgotten—but we had to select this yard because it had gates at each end, and therefore we could get out without having to turn round in the yard. I presume Messrs. Maudsley simply followed directions, but however this may be, the driving wheels of the traction engine were both of them keyed on the shaft hard and fast as though they had been the paddle wheels of a steamer, with the result that it was impossible to make a curve of a small radius. I doubt whether this traction engine (for such it was) worked more than experimentally for one or two seasons.

The boiler of Summers and Ogle is strictly a water-tube boiler. The tubes are vertical, and have each an internal tube, giving therefore an annular water space. The external vertical tubes are connected at their top and bottom in transverse tubes which, I believe, were of a ▭ section—the lower ones to make the water connection, the upper ones to make the steam connection, while the internal tubes served as stays to join the vertical and horizontal tubes together. This boiler was made of charcoal iron, was proved to 364lb. on the square inch, and ran at 240. The boiler weighed 8½cwt., and had 245ft. of heating surface, including the portion which was occupied by the steam. The iron was $\frac{1}{16}$in. thick. This coach worked very successfully in a variety of long and short journeys, but, like all the rest, was eventually abandoned.

Macerone and Squire's boiler is practically Summers and Ogle's boiler—that is to say, vertical water-tubes—but with the internal tubes omitted, and with the side tubes longer than the tubes in the middle, so as to form a partial external wall to the fireplace. Colonel Macerone was a powerful man with his pen, and those who are interested in the subject of steam locomotion, and are willing to take it from Colonel Macerone's point of view, are referred to a pamphlet published by Effingham Wilson, Royal Exchange, and George Herbert, Cheapside, in 1835. There is another pamphlet by Macerone, I believe, in the following year, called "Macerone *v.* The Mechanics' Magazine," which may interest students of the subject The carriage ran very successfully, but it was eventually abandoned.

The boiler of the Church coach was first made in a water-jacketed horizonal portion of the boiler, which at its higher end carried a vertical cylinder having a bottom tube plate, through which rose a number of vertical tubes, which at their top ends, as I remember was said at the time, turned over and outwards like the supports of the ribs of an umbrella, and thus were enabled to pierce the sides of the vertical boiler, and to obtain access for the products of combustion which had passed through them to a circular flue space surrounding the vertical part of the boiler. In an alternative plan the vertical part of the boiler had an internal cylinder, leaving only a thin annular water space. Near the bottom of this inner cylinder small tubes issued, and were bent upwards so as to rise vertically through the top plate of the cylinder. These were true water-tubes. The products of combustion arose between these tubes, and escaped by outlets made through the annular water space into the circular flue, which, as in the previous instance, surrounded the boiler. My recollection is that these boilers, or one of them, was put into a coach, or coaches, which actually ran, but I cannot find any particulars of the journey.

The Griffith was constructed by Messrs. Bramah for Mr. Griffith. The carriage is stated to weigh 3½ tons, and was destined to carry three tons of merchandise, but I have no account of its running. The boiler consisted of two flat vertical water-chambers, placed one on each side of the fire, and connected together by horizontal water-tubes—2ft. long and 1¼in. in diameter—of which there were 114. The boiler never could be kept tight, and the whole thing was a failure.

The Scott Russell is the last steam coach of which I intend to give any description. As many as seven or eight were built to run between Glasgow and Paisley. These coaches had been running some time when, on July 29th, 1834, one of them exploded as it was starting from the Halfway House. Three persons were killed, practically on the spot, and I believe two or three of the wounded died afterwards. Mr. Scott Russell did not take out any patent for his boiler except in this sense, that he patented a cubical vessel made of extremely thin flat sides, but strengthened by innumerable tie-rods going from side to side. I believe he suggested one for each square inch. He shows no other drawing than this typical vessel, but says, in effect, it would be easy to apply his principle when flues, etc., are introduced for the purpose of employing the vessel as a boiler. I believe this construction was adopted in the coaches before mentioned.

My last reminiscence of a passenger steam carriage on common roads is a comparatively recent one. I refer to the carriage constructed by the late Mr. Loftus Perkins. This was purely experimental; it carried only two or three persons. The boiler was the well-known "Perkins" water-tube boiler; the engines were compound, and with the boiler were carried on the framing of the single steering wheel (it was a three-wheeled vehicle), which was also the driving wheel, so that the crankshaft was always normal to the direction in which the carriage was going.

When speaking of Hancock, I gave him the credit for being the introducer of diminishing "priming," by the use of very small steam-pipes. Perkins, with this high-pressure steam of some 600lb., carried this principle to a still greater extent, and he was in the habit of wearing on his watch-chain a piece of pipe having a bore of only $\frac{1}{8}$in, through which he had taken the steam for 40 h.p. I am informed by a letter from Mr. Perkins's son that this engine is still in use at the Gypsum Works, near Battle.

I do not make any reference to Nairn's carriage, which ran for a long while between Edinburgh and Leith. I do not refer to this because, although, no doubt, it is one of my reminiscences, it is one of so recent a date that it must be included among your reminiscences Neither do I propose to enter into the description of the competition among the self-moving road vehicles in France, but I am glad to see, from the illustrations in the technical papers that the French have appreciated the desirability, indeed the need, of constructing the vehicles in a manner that should not shock the susceptibility of horses; and as one who is, and always has been, much interested in this subject of steam locomotion on common roads, I am very glad to find that it has been taken up by our neighbours, who, having regard to their great engineering ability and their consummate taste, should of all people be likely to obtain a successful result.

THE HISTORY OF WOODHOUSE AND RAWSON UNITED, LIMITED,

As Detailed in the Bankruptcy Court.

MONDAY.

The public examination of the directors and officers was resumed on Monday, before Mr. Registrar Hood, at Bankruptcy-buildings, Carey-street. Lincoln's-inn.

Mr. F. L. Rawson the managing director, was further examined by the Official Receiver. He said that in February, 1891. a prospectus was issued inviting applications for debentures. One of the statements in the prospectus was that "the debenture stock will, upon the existing debentures being paid off, which will be done by the directors as soon as possible, become a first charge on the entire undertaking." A circular was also issued with reference to the same debentures, which stated that the debentures would be secured as a first charge on the whole of the Company's undertaking, there being no qualification. The circular and the prospectus were sent out together, and, although witness could not say that every applicant had received both, he was certain that all those who did apply (being for the most part original debenture-holders) were fully alive to the actual position of matters.

The **Witness**, examined by Mr. Pilling, said that he had never been repaid the loan of £5,000 made by him to the Phœnix Trust. He had a running account with the trust, but they were nearly always in his debt. The United Company took no risk, in his opinion, in regard to the promotion of the American Elmore Company. An agreement was entered into whereby the United Company undertook to form the company, but witness said the legal construction of the document was open to argument. The Phœnix Trust underwrote a great number of shares in the Elmore Company, and received £34,000 as their commission in the matter. When the affairs of the Phœnix Trust were wound up. the shares held by the trust were distributed amongst the shareholders. The United Company and witness received a portion of deferred shares in the American Elmore Company, but he did not think it was the fact that no other persons interested received deferred shares. Questioned with reference to the prospectus of the Company, witness said that the Board of the old company were responsible for the estimate of the profits (£75,000) for the year 1889, and, as a member of that Board, he was willing to accept any responsibility which might be attached thereto. The estimate was prepared at the instance of the new directors, and the accountant reported that it was a fair one. As a matter of fact the profit proved to be £78,000, and he therefore considered that the estimate was carefully and correctly made. He denied that the sum to be divided amongst the shareholders of the old company was £348,000. His personal account with the United Company showed transactions amounting to £83,000. An advance of £28,000 was made to him for the purpose of paying for shares which he had acquired in the Company at a premium of 5s. per share, the shares being deposited as security, and an assignment of his interest in founders' shares of the old company being also made to the United Company. He had throughout steadily increased his shareholding in the concern.

Digitized by Google

He had never received any remuneration in respect of the formation of the new company.

Mr. Registrar Hood invited witness to make a statement as to the representations made in the prospectus as to the financial portion of the Company's business, and pointed out that although the powers conferred by the memorandum of association were very wide, there was very little said in the body of the prospectus as to the extent the financial busines would be conducted.

Witness then entered upon a lengthy statement as to the past history of the Company. He said that testimonials had been given by Government officials and others of the high class of work turned out by the Company. In some departments of the business they were without rivals.

Mr. Registrar Hood said that, notwithstanding the great skill which the Official Receiver had exercised in presenting the complicated story of the Company, there might be certain facts of importance which had not been brought out. If any of the persons who had been examined thought it desirable to place further facts before the Court, he would grant them a supplementary sitting.

Mr. F. L. Rawson next gave an explanation by way of re-examination as to his connection and transactions with the Company. He denied that the Company had ever acted as promoters of other companies, although they had assisted in the formation of companies for the working of electrical patents only. Great care had been exercised in the formation of the United Company, the new directors being most particular with regard to the information supplied to them. He had given to the Company the option of a call on certain shares in the Elmore Company, which ultimately proved to be worth £35,000. A suggestion had been made that the business of Woodhouse and Rawson was insolvent in 1885, but there was not the slightest ground for it. At the time the Company was formed it was not contemplated that the financial business would grow to such an extent as it had done. Witness had hoped that within three years the industrial portion would have so developed as to enable the directors to pay a dividend of 5 per cent. on that branch alone. Witness said that he had endeavoured not to further his own interests in any way except by the successful working of the Company.

WEDNESDAY.

The case stood over on the last occasion to enable Mr. F. L. Rawson to make a complete statement as to the part he had taken in the Company's transactions and affairs, but he now said that his notes on the case were very voluminous, and it would take him some time to read the statement. He suggested that he should be permitted to put in the draft materials for his statement, and to address the Court on certain points which he desired to amplify.

The **Official Receiver** said this course would be most inconvenient, because the statement could not be used as evidence against other persons.

Mr. Jenkins suggested that the course to be adopted would be to allow Mr. Rawson an opportunity of putting in his statement in full, and if any questions arose upon it, an application might be made for a further public examination.

Mr. Registrar Hood adopted the view suggested by the learned counsel, and said the case would be mentioned formally in Chambers on the 15th inst., when Mr. F. L. Rawson could put in his statement.

Mr. Jenkins then examined the **Witness** with reference to the balance-sheet issued by the Company in 1891. He said that 25 founders' shares in the Phœnix Trust were included in the accounts at £15 000. He satisfied himself that if the trust had gone into liquidation then the shares would have produced that amount. As a matter of fact, the United Company were in a position to put the trust into liquidation, but refrained from doing so because it was about to bring out the American Elmore Company, from which it was anticipated that a considerable profit would accrue to the United Company. The American Elmore Company being successfully floated, the United Company realised the profit. The subject of the Epstein shares taken in the balance-sheet as of the value of £35,000 was considered by the Board very carefully, and they asked witness whether he could refer them to any expert who could give an opinion as to their value. Witness could not do so, but assured the directors that they were worth the sum mentioned. He offered to buy £3,000 worth of the same shares at par. Shares in a Spanish company were taken at the quotation upon the Barcelona Bourse. The amount of £5,000 paid to the United Company by the Phœnix Trust as their share of the profit made on the formation of the Austro-Hungarian Elmore Company was received in shares, which were quoted in the financial papers at that value. Witness devoted his time and attention almost entirely to the financial side of the business, and laid the various patents and negotiations before the Board, and, if they were approved, the details of working them out devolved upon him. Sir Rawson W. Rawson and Sir John Stokes interested themselves in the industrial portion of the business more than in the financial part, and endeavoured to get the affairs of the old company wound up.

Questioned by **Mr. Pilling** with reference to the option to call for Elmore shares which he stated on the last occasion he had given up to the Company, **Witness** said that he originally gave it to the old company, and when the new company was formed the directors claimed it. Their claim was disputed, and the matter was ultimately settled in favour of the new company.

The **Official Receiver** asked that in the event of further questions arising he should have leave to apply for a further sitting for public examination.

His **Honour** granted the application, and the enquiry was then adjourned generally.

COMPANIES' MEETINGS.

UNITED RIVER PLATE TELEPHONE COMPANY, LIMITED.

The ordinary general meeting was held last week at Winchester House.

Mr. J. Irving Courtenay (the chairman), in moving the adoption of the report, said the business of the Company during the past year showed a decided improvement. They had gone through another very trying period of disturbance political and monetary, and it might reasonably have been expected that the number of subscribers would have fallen off but, on the contrary, there had been an increase of 606. They had to make some addition to the salaries of their employés, the full effect of which had yet to be felt. The loss on exchange was enormous, and for the year under review it amounted to £54,124, the highest figure yet reached. So far as the past year was concerned, it swallowed up the larger part of the profit that otherwise would have been available for distribution among the shareholders. The net profit, after paying the debenture interest and all other charges, was £9,782. The Board had allocated to certain accounts the sum of £4,270, of which the principal item was £3 000 transferred to depreciation and renewal fund. The net balance to be carried forward to next year was £6 417.

Mr. Frank W. Jones seconded the motion for the adoption of the report, which was carried.

COMPANIES' REPORTS.

CROMPTON AND CO., LIMITED.

Directors: Viscount Emlyn (chairman), Rookes Evelyn Bell Crompton, Esq., and John Francis Albright, Esq. (managing directors), H. H. J. W. Drummond, Esq., Bernard Gibson, Esq., Carleton F. Tufnell, Esq.

Sixth report of the directors to be presented at the annual general meeting of the shareholders at the City Terminus Hotel, Cannon-street, E.C., on Monday, August 13, 1894, at 3 p.m.

The directors beg to submit the sixth annual statement of accounts made up to March 31 last. The amount of the Company's business has satisfactorily increased, but the net profits, in consequence of close competition, show a reduction as compared with last year, and this notwithstanding the fact that the directors by careful management have reduced the expenses in many departments. The net profits for the year amount to £11,741. 2s. 7d., and after providing for debenture interest, and the payments set out in the revenue accounts, there remains a balance of £6,116. 3s. 5d., out of which the directors propose to set aside £1,000 for contingencies and doubtful debts, to pay a dividend of 3s. per share on the preference shares, and to carry forward the balance. The directors regret that the net profits are insufficient to allow for the full dividend on the preference shares; at the same time they do not think there is anything discouraging as to the future of the Company. The works are in first-rate order and condition, and under the new management the cost price of manufacture has been considerably reduced, while the various departments outside the works are at the same time being carefully reorganised with the view of reducing expenditure to the utmost without affecting their efficiency. Since April, 1891, the directors have entered into no contracts whatever under which the payments for work done were to be partly made in shares or securities, but they feel that the value of some of the securities previously taken as part payment may be considered doubtful. Recognising the necessity of reducing such doubtful assets or securities to their proper value in the Company's books, they propose that an amount of £20,000 shall be written off, and to enable this to be done they have obtained the assent of the two managing directors, Messrs. Crompton and Albright, to relinquish an equal amount of ordinary shares. The effect of this transaction will not be to deprive the Company of any value which the securities in question may hereafter attain, and the reduction of the amount of ordinary shares must be for the benefit of the members generally. The directors are glad to be able to report that the cooking and heating department of the Company, which has been practically established during the past year, is likely, in their opinion, to prove a very valuable addition to the Company's business. The directors, in response to their circulars in January last with regard to the proposed issue of £100,000 of 4½ per cent. debentures, have received promises from the debenture and share holders of the Company to subscribe for the new issue to the amount of nearly £32,000, but as this support was insufficient to enable the issue to be made with any certainty, the Board considered it better to wait for the statement of accounts now presented. It is intended to take further steps to place the debentures during the ensuing autumn, but they wish to urge upon the shareholders that it is in their own interests to assist in this issue, which is of such great importance to the Company. At the same time, they would remind the shareholders that the security for these debentures is undoubted. The property of the Company, even after the reductions before referred to, amounts to £236,618, including uncalled capital, but without reckoning the value of patents and goodwill, and the income of the Company for the last six years has averaged £11,839 per annum, while the interest required for the total proposed issue of debentures would only amount to £4,500 per annum. In accordance with the articles of association, the chairman, Viscount Emlyn, retires from the board of directors by

Digitized by Google

rotation, but offers himself for re-election. The auditors, Messrs. J. H. Duncan and Co., also offer themselves for re-election.

STATEMENT OF LIABILITIES AND ASSETS AT MARCH 31, 1894.

Capital and Liabilities.	£	s.	d.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY, LIMITED.

Directors: Joseph Ebbsmith, Esq. (chairman); William Neale, Esq.; B. J. Round, Esq.; John Booth, Esq.

Report of the directors to be submitted to the shareholders at the thirteenth ordinary general meeting, to be held at the Queen's Hotel, Stephenson-place, Birmingham, on Wednesday, August 15, 1894, at 12.30 p.m.

Working Accounts.—The working profit for the past year, omitting the Corporation charges for maintenance, amounts to £52,804. 8s. 11d., as compared with £50,424 1s. 10d. for the year ended June 30, 1893, showing an improvement of £2,380. 7s. 1d. The Corporation charges for maintenance, however, have again advanced by the sum of £1,729. 14s. 11d., which reduces the net comparative increase of working profit to £650. 12s. 2d. For the information of the shareholders, the total amount of the Corporation charges for maintenance for the past year (£8,699. 15s. 11d.) has been debited as a distinct item to revenue account, instead of being apportioned between the various departments as heretofore. This transfer gives an apparent proportionate increase of the profits upon the working accounts, which might be misleading without this explanation.

Revenue Account.—The revenue account shows a balance of £24,978. 3s. 5d., to which has to be added the sum of £3,438. 6s. 9d. brought forward from last year's account, making together £28,416. 10s. 2d.

Application of Profits.—Your directors recommend (1) that the sum of £10,000 be placed to reserve account against depreciation; (2) that the payment of the dividend upon the 5 per cent. guaranteed shares, amounting to £5,000, be confirmed; (3) that a dividend of 2½ per cent. upon the ordinary shares of the Company, amounting to £9,700, for the year ending June 30 last, be declared and paid on September 1 next; (4) that the balance of revenue account, amounting to £3,716. 10s. 2d., be carried foward.

Balance sheet.—The balance-sheet shows the position of the Company to be one of assured and increasing strength and security, but the directors impress upon the shareholders the wisdom of dealing boldly and speedily with those items of capital expenditure which are not now fairly represented by assets of the Company, and to which reference is made year by year in the auditors' report.

Directors.—Mr. Martyn J. Smith, much to the regret of his colleagues, owing to pressure of other engagements, retired from the Board in February last. Mr. John Booth and Mr. Ebbsmith are the members of the Board now retiring by rotation, and being eligible offer themselves for re-election.

Auditors.—Messrs. Howard Smith, Slocombe, and Co. retire, and are eligible for re-election as auditors of the Company.

The auditors, Messrs. Howard Smith, Slocombe, and Co., chartered accountants, report: "We have examined the books of account, vouchers, and other documents relating to the accounts of the Company, and find the foregoing statements to agree therewith. We are informed that it is the intention of the directors to add, out of the profits, a sum of £10,000 to the reserve against depreciation of assets, and we are of opinion that such addition is sufficient for the depreciation of the year, as regards all assets other than leasehold lines and parliamentary concessions, which apparently represent over £300,000 of the capital expenditure, and the present value of which we cannot estimate. With the foregoing explanation we believe the balance-sheet to be a complete and fair statement of the assets and liabilities of the Company, and the revenue and working accounts to truly set forth the transactions of the past year. (*See also special report.*)"

AUDITORS' SPECIAL REPORT.

Our attention has been called to the paragraph headed "Balance-sheet" in the report of the directors, and we are informed that it is their intention to recommend a reduction of the ordinary share capital of the Company for the purpose of reducing by a corresponding amount that portion of the capital expenditure which is

Digitized by Google

not represented by any tangible assets or by goodwill. We fully concur in the wisdom of this course, and are strengthened in our opinion by the revaluations of the property and rolling-stock which the directors have laid before us. These show that the sums set aside as reserve against depreciation must be wholly applied for the tangible assets, and would not, in fact, be sufficient in the event of their immediate realisation. However substantial and regular the future profits may be, it cannot be expected that they will yield a margin sufficient to provide for the whole of that portion of the capital expenditure (over £300,000) to which special reference has been made in our reports on the accounts of this and previous years.

CONTRACTS FOR ELECTRICAL PLANT.

CONTRACTS OPEN.

Lancaster.—The surveyor to the Town Council has been instructed to obtain tenders for arc lamps for street-lighting.

Ottawa.—The Canadian Government, under the authority given it by the recent Inter-Colonial Conference, is inviting tenders from cable-manufacturing contractors for the laying and maintenance in an efficient condition of a cable across the Pacific from Canada to the Australasian colonies. Offers will be received to 1st November next.

Newcastle-on-Tyne.—Tenders are invited by the 15th inst. for the best scheme, with cost, for the lighting and heating of New Trinity Presbyterian Church, to be built in Northumberland-road. Plan may be seen and other particulars obtained from the architects, Messrs. Marshall and Dick, 4, Northumberland-street. Tenders are to be sent to Mr. J. Fulton, secretary, Building Committee, 20, Jesmond-road

London, N.W.—The St. Pancras Vestry require by the 16th inst. tenders for the supply and laying of armoured cables. Specifications, schedules of quantities, general conditions, and plan of streets can be obtained at the offices of Prof. H. Robinson, 13, Victoria-street, Westminster, on payment of 5s. Tenders must be sent to Mr. Alfred E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras road, N.W.

Sunderland.—The Corporation of Sunderland require by the 16th inst. tenders for the supply of grip-boxes and connectors. Those desirous of tendering should send in their names and addresses to the Electrical Engineer, Electric Light Station, Dunning-street, Sunderland, and copies of drawings, specification, and form of tender will be forwarded to them on receipt of 10s 6d. Tenders, addressed to the Chairman of the Highways Committee, and endorsed "Electric Lighting Grip-boxes and Connectors," are to be delivered at the office of Mr. Fras. M. Bowey, town clerk, Town Hall, Sunderland.

RESULTS OF TENDERS.

Yarmouth.—The following tenders were received for the electric lighting of the School of Art, South Quay: Messrs. Crampton, of Cambridge, £57. 18s. 6d.; Messrs. Laurence, Scott and Co., £81. 16s. 4d.; Messrs. Crompton and Co., £86. 5s.; and Mr. Durrant, of Yarmouth, £96. 17s. 11d. The tender of the first mentioned was accepted.

BUSINESS NOTES.

Tynemouth.—The aquarium is to be lighted by electricity.

Alderley Edge.—The Local Board intend to apply for a provisional order.

Great Northern Telegraph Company.—For the month of July the receipts were £25,600.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,335.

Douglas.—The number of passengers on the electric railway averages now about 30,000 per week.

Coventry.—The sum of £1,200 is to be borrowed by the Town Council for electric lighting purposes.

Plant for Sale.—It will be seen by our advertisement columns that some second-hand electrical plant is for sale.

Stroud.—The Local Board of Health are to provide electric calls for their own brigade and for the volunteer fire brigade.

Eastern Telegraph Company.—The receipts for the month of July were £56,753, as against £62,317 for the corresponding period.

Wigan.—Improvements have been made at the Royal Court Theatre, and also arrangements for an installation of the electric light.

Tunbridge Wells.—The Local Government Board have sanctioned the borrowing by the Town Council of £13,000 for electric lighting purposes.

Colchester.—The Town Council have sealed a contract with Messrs. Christy Bros. for lighting the public library building by electricity.

Direct Spanish Telegraph Company.—For the month of July the receipts were £1,400, as against £1,656 for the corresponding period of last year.

Cuba Submarine Telegraph Company.—For the month of July the receipts were £133 less than for the corresponding period of last year.

West India and Panama Telegraph Company.—The receipts for the two weeks ended July 31 were £27 less than for the corresponding period.

Shoreditch.—The Board of Trade have intimated to the Vestry that they will give them another year's grace for the carrying out of the electric lighting order.

Eastern Extension Telegraph Company.—For the month of July the receipts show a decrease of £2,503 as compared with the corresponding period of last year.

Dundee.—The estimates of the Police Commission for the year ending May, 1895, have been submitted. They include the item of £200 for lighting the High-street by electricity.

Sunderland.—The Highways Sub-Committee of the Sunderland Corporation have decided to recommend that the price charged to customers for the electric light shall be 6d. per unit.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 5th inst. amounted to £1,000, as against £858 in the corresponding week of last year.

Denbigh.—The Lighting Committee of the Town Council have had referred back to them for consideration the subject as to the best steps to be taken for the introduction of electric lighting.

Windermere.—The Local Board have received formal notice from the Windermere and District Electric Light and Power Agency of their intention to apply for power to introduce the electric light within the Board's district.

Perth.—The Town Council have unanimously refused to consent to the application made by the Municipal Electric Light and Power Corporation, Limited, and the Caledonian Electric Supply Company, Limited, under the Electric Lighting Acts, 1882 and 1888.

Matlock Bath.—Business relating to the settlement of the boundaries between the two districts of Matlock has been discussed by the Matlock Bath Local Board. The chairman incidentally stated that they must retain the weir for the purpose of electric lighting.

Worcester.—The Mayor, Mr. G. H. Williamson, has announced that he has been in communication with Mr. Preece, consulting engineer, and with the Brush Company, about the opening of the electric station, and October 11 has been fixed for the opening ceremony.

Change of Address.—Mr. Gisbert Kapp informs us that from the 14th inst No. 31, Parliament-street, Westminster, and "Erba," Wimbledon-park, will cease to be his addresses. Mr. Kapp's new address from October 1 will be 3, Lindenallee, Westend, Berlin.

Winchester.—The Electric Light and General Purposes Joint Committee have resolved to recommend the Town Council to apply for a provisional order to light the city by electricity. The order will cost about £300, and the works will necessitate a loan of about £20,000.

St. Pancras.—In consequence of the demand for current in the district north of the Cobden statue having exceeded that contemplated when the mains were originally put down, the St. Pancras Vestry have decided to expend £2,800 in putting down supplementary feeders and mains.

Bridlington.—The North Cliff has been lighted for the first time by electricity. There are seven arc lamps of 1,200 c.p. each, and they extend from the north end of the Prince's Parade to Trinity Cut. The work has been carried out by Mr. R. Railston Brown, the Board's surveyor.

Burton.—The consumers of the electric light are increasing. Whereas in February a start was made with 13, there are now 40, and there is reason to believe there will be an additional influx in the autumn. Lord Burton has intimated his intention of defraying the costs of electric lighting in the municipal offices.

Walthamstow.—The Local Board have unanimously resolved to take steps to obtain a provisional order for lighting the district with electricity, Mr. J. H. Wildash (the chairman) and other members, commenting upon the attitude of the gas company towards the Board and the high price charged for the gas.

City and South London Railway.—The receipts of the Company for the week ended August 5 were £848, against £804 for the corresponding week of 1893, or an increase of £44. The total receipts for the current period of the present half-year amount to £4,306, as against £4,237 in the corresponding period of 1893.

Salford.—At a meeting of the Salford Town Council Mr. Holland (chairman of the Gas Committee), in reply to Mr. Alderman Dickins and Mr. Alderman Mottram, said he could not give the price at which the electric light would be supplied to residents. He thought the installation would be complete in time for the winter.

Halifax.—Now that the Halifax Corporation are preparing to supply the electric light, it is felt by a section of the Town Council that the installation ought to begin "at home," and are therefore urging the lighting of the Town Hall and its precincts by electricity. A sub-committee has been appointed to consider the matter.

Huddersfield.—An electric light installation has been completed at the premises of the Huddersfield Industrial Society. There are 14 2,000-c.p. arc lamps outside the buildings, and 34 1,500-c.p. arc lamps and 270 incandescent lamps inside. The installation has been carried out by Mr. John Edmundson, of Huddersfield.

Kendal.—Some months ago notice was given to the Town Council by a company of their intention to apply to the Board of Trade for a provisional order to supply electricity in the district

Digitized by Google

under the Electric Lighting Act. That notice has now been withdrawn and another substituted by the Windermere and District Electricity Supply Company.

Newcastle.—A special committee of the Corporation on Tuesday decided to invite Prof. Kennedy to visit the city and give his advice on the subject of lighting the streets electrically. At the same meeting a letter was read from the Newcastle Electric Supply Company on the subject. The Eldon Hotel has been reconstructed and is now lighted by electricity.

Tottenham.—The Local Board have decided, on the recommendation of a committee consisting of the whole Board, to apply for a provisional order. A special committee of five members has been appointed to consider the subject, with power to confer with authorities who have adopted electricity for public lighting with a view to obtaining information.

Leeds.—The congregation at the Leeds Parish Church on Sunday night had the opportunity for the first time of seeing the edifice illuminated by means of the new electric installation. In all there are 245 incandescent lamps, and about half that number were in use at the evening service. Messrs. Laing, Wharton, and Down, of London, were the contractors.

Colliery Plant.—Messrs. J. P. Hall and Co., of Oldham, are carrying out an electrical power transmission plant for a colliery, consisting of a dynamo to give 250 amperes at 600 volts when running at 400 revolutions per minute, and several motors for pumping and other purposes. The largest of these motors is of 70 b.h.p., and will be situated at about 900 yards from the surface.

Sunbeam Lamps.—The Sunbeam Lamp Company, Limited, of Gateshead, remind the trade, now the season for electric lighting is approaching, that they are now manufacturing small incandescent lamps as well as their well-known large Sunbeam lamps. The lamps are of English manufacture, and range in small lamps from 8 c.p. to 50 c p., and in the case of large lamps from 100 c.p. to 2,000 c.p.

Sutton (Surrey).—At a meeting of the Local Board the Chairman called attention to the fact that the electric lighting order which was granted by the Board of Trade expired in June last, and asked what the Board intended to do. The Clerk said he understood the Board of Trade would not grant an extension of time, but would not entertain any other application without first communicating with the Board.

Abergavenny. — The chairman of the Improvement Commission, referring to the report as to lighting Abergavenny by electricity, said it was a bulky report which the expert had prepared and sent in, some 40 sheets, and he would suggest that it should be open to the inspection of any ratepayer who might like to see it at the clerk's office any day between ten and five. The chairman's suggestion was adopted.

Oswestry Electric Lighting Company.—Arrangements have been made by the Oswestry Electric Lighting and Power Company, Limited, to guarantee a minimum dividend of 3 per cent. per annum upon the share capital up to £4,000, such guarantee to be in force for a period of three years from the date of the first supply of electricity to the town by the Company, and not to apply to the shares held by the present chairman.

Belfast.—The report of the Electric Committee stated: "Your committee have accepted the tender of Messrs. Marshall, Fleming, and Jack for the supply and erection of an overhead travelling crane for the central station. They have to report that the various contractors are pushing on with the works vigorously, and your committee expect all the contracts will be completed within the specified time." The report was agreed to.

Gravesend.—Gravesend is at last to have a telephone exchange. The directors of the National Telephone Company have decided to commence operations forthwith, and hope to have the system in operation at an early date. In addition to the local systems communication will also be established by means of special trunk wires with Chatham, Rochester, Strood, Maidstone, and numerous towns in East Kent, and London, Liverpool, Manchester, and northern towns can be spoken to.

Darlington.—Mr. Barron, in moving the adoption of the Gasworks Committee's report, at a meeting of the Town Council, referred to the great consumption of gas and the probable necessity of enlargement. This might be obviated if it were decided to introduce the electric light. There was no antagonism to the electric light on the part of the Gasworks Committee, and if it saved the extension of the gasworks money would be also saved by preventing the necessity of obtaining borrowing powers.

Luton.—An installation of the electric light has been carried out at the Public Benefit Boot Company's establishment, Park-square. The lighting is effected by means of a 3 h p. Tangye gas-engine and a three-unit dynamo. These are placed in the cellar beneath the shop. The dynamo will feed two arc lights of 2,000 c p. and 30 incandescent lamps of 16 c p The installation has been carried out by Mr. W. J. Barrett, of Luton, superintended by the General Electric Company, Limited, London.

Royal Lunatic Asylum Aberdeen.—This institution is at present undergoing extensive alterations involving the reconstruction of the old buildings and the erection of a new hospital. When completed, the whole will be lit electrically by generating plant on the premises. Messrs. New and Mayne have secured the first electrical contract placed; this is for the wiring of the new building to the plans and specifications of Dr. R. Mullineux Walmsley, of Edinburgh, the consulting electrical engineer of the Asylum Corporation.

Eastbourne.—The existing gas fittings at the parish church have been in use for nearly 30 years, and the joints and pipes are in a condition to require continual attention and repair. Under these circumstances it has been decided to introduce the electric light. The following is the approximate outlay: for laying the wires in the church and connecting with the mains, £90; for fittings, £85; extras (removing gas standards, etc.), £25; total (approximately), £200. The work will probably be completed and the electric light in use on or about the first week in September.

Cardiff.—A meeting of the sub-committee appointed by the Cardiff Free Library Committee to consult Mr. Massey as to the best plan for lighting by electricity the new free library building has been held at the Town Hall. Mr. Marcus Gunn presided, and Mr. Seaward, Mr. Massey, and Mr. Ballinger were present. Mr. Massey would not give any advice without seeing sketches of the furniture and plans of the rooms, and also full particulars as to the area. This will be supplied to him, and he will in due course give the advice needed and estimate of the cost of the undertaking

Lancaster.—The Town Council have decided to raise the salary of Mr. A. Barnard, the electrical engineer, from £120 to £150 per annum. An electrical cookery demonstration is to be given at the Storey Institute by Messrs. Crompton. The Town Council will provide a room, the current, and the services of the electrical engineer. The Council have resolved not to keep in stock electric ovens, etc., for sale or letting out on hire. The price for the supply of current for cooking purposes has been fixed at 7d. per unit. The question of electric street-lighting is to be considered by a committee.

Yarmouth.—Fair progress is being made with the public electric light installation. The standards for the lamps are already in place along the Parade, in Regent-street, King-street, and in the Hall Quay Gardens. The mains have been placed underground, and are already down for the Parade lamps, while the finishing touches are being rapidly given to those deposited in King-street. In this street the cables are being laid under the pavement on either side of the street. Portions of the dynamos and the engine plant have arrived at the generating station on the South Denes, and the workmen are busy in their erection.

Andrews and Preece, Limited.—Mr. Justice Chitty, in the Chancery Division on Saturday, gave judgment in the action of the Halifax and Huddersfield Union Banking Company, Limited, *v.* Andrews and Preece, Limited. This was a debenture-holder's action, and a receiver and manager has already been appointed, as stated in our issue of the 27th ult. The Company now appeared, and admitted that they had no defence. His lordship accordingly declared the plaintiffs entitled to an account of what is due for principal and interest, and to an enquiry what property was comprised in the debentures, with liberty to apply in Chambers as to a sale.

Crompton and Co., Limited.—An extraordinary general meeting of the shareholders will be held at the City Terminus Hotel, Cannon-street, E.C., on Monday next, the 13th inst., at 3.30 p m., or so soon as the business of the ordinary general meeting convened for the same day shall have been concluded, for the purpose of considering, and if approved of passing, the following special resolution: "That the capital of the Company be reduced from £300,000 to £280,000 by cancelling paid up capital which has been lost, or is unrepresented by available assets, to the extent of £20,000 by cancelling 4,000 ordinary fully paid-up shares of the Company, numbered 2,785 to 6,784 inclusive which have been issued."

Appointments Vacant.—The Corporation of Dewsbury require by the 17th inst. a qualified practical electrical engineer to take charge of the new electric lighting station and works at Dewsbury. Applications, stating age, qualifications, present employment, and salary required, accompanied by not more than three testimonials, are to be sent to Mr. E. Mawdesley, town clerk, Town Hall, Dewsbury, endorsed "Electrical Engineer." The Electricity Supply Company for Spain, Limited, require a thoroughly competent assistant electrical engineer for their Madrid station. He must be able to go out at once. Further particulars are given in our advertisement columns.

Canterbury.—At a meeting of the Town Council the General Purposes Committee reported that they had received a letter from Messrs. Mowll and Mowll, on behalf of the electric lighting company, asking what amount of street and public lighting the Corporation would give to the company. Alderman Mount proposed that a letter be written asking how many ordinary lamps an arc lamp would displace, so that the Council could get at the probable number required, and the cost. Alderman Mason remarked that before the company had some assurance they were not prepared to take over the order and pay the £400. Without it the Council would have to keep their order. The motion was carried.

Clerkenwell.—In our issue of the 27th ult. we recorded the fact that the County of London Electric Lighting Company had given notice to the Vestry that they are about to lay conduits for electric conductors under the County of London (North) Electric Lighting Order, 1892. The Vestry have decided that the company be required to relay the disturbed paving to the satisfaction of the Vestry's surveyor, and to be responsible for its condition for a period of three years. The letter from the Board of Trade, forwarding copy of the regulations and conditions for securing the safety of the public which they propose to issue under the same order, was considered, but the Vestry did not deem it necessary to make any observations thereon, and the Board of Trade has been so informed.

Foliated Brushes for Dynamos.—The Boudreaux Dynamo Brush Company, of 1, Gresham-street, E C, have forwarded us a list of firms who use their new foliated brushes. Among these

Digitized by Google

may be mentioned no less than nine English electric supply companies, and some of the most important manufacturing firms, whilst this type of brush has also been adopted in some large private installations. The testimonials contained on the list show the high esteem in which these brushes are held. We are informed that 50,000 of these foliated brushes were adopted by 1,500 users in France alone during the second year of their being brought out. The company are also agents for Labour's self-exciting alternate-current generators and transformers, and direct-current dynamos made under Rechniewsky's patent.

Gloucester.—The minutes of the City Council stated that the town clerk reported that he had received from the undermentioned companies formal notices of intention to apply to the Board of Trade for a provisional order to supply electricity for public and private purposes within the city of Gloucester: the County of London and Brush Provincial Electric Lighting Company, Limited; the Great Western Electric Light and Power Company, Limited. Alderman Holtham, in drawing attention to this, said he understood the Corporation had themselves applied for a provisional order; if not, they ought to oppose the applications of these companies, as if anything was to be made out of supplying the city with electric light the Corporation ought to get the benefit of it. The Town Clerk said it was understood the Council refused the applications made by the companies.

Hastings.—The Roads Committee of the Town Council have reported that they had received from the secretary of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, formal notices in accordance with the requirements of section 14 of the company's provisional order of the intention of the company to construct in connection with their works two circuit chambers under the public pavements—viz., one opposite the Royal Saxon Hotel at the bottom of London-road, and the other at the upper side of the junction of Silchester-road with London-road—as shown on plans. The plans for the chambers have been approved by the Council, subject to the works being carried out to the satisfaction of the borough surveyor, and to the company undertaking not to remove the upper surface or cover of either of the chambers except between the hours of 10 p.m. and 9 a.m., unless in case of actual emergency.

Aberdare.—On Tuesday evening a meeting was held at the Boot Hotel to arrange for the electric lighting of the centre of the town. Mr. D. Williams, the high constable of Aberdare, presided, and Mr. J. C. Howell, of Llanelly, in an exhaustive speech, explained the present position of affairs. Some 12 months ago Mr. G. George, J.P., consulted them as to the possibility of forming a co-operative scheme for the lighting of the business premises in the town. They found that this project was impracticable, and applied to Parliament for a provisional order to light the centre of the town. This had now been obtained, and the purpose of that meeting was to make arrangements for the formation of a company to carry out the provisions of the provisional order. After a lengthy conversation an influential committee was appointed to visit Pontypool, and to report to a subsequent meeting. Mr. P. T. Rhys acted as the solicitor for the promoters.

Kingston-on-Thames.—The minutes of the Lighting and Market Committee of the Town Council stated that tenders were opened for the supply of a gas or oil engine for the electric lighting works, and it was resolved that the tender of Messrs. Robey and Co., at £126, be accepted. The borough electrical engineer was directed to alter the arc lamps in the Market-place at Mr. Whaley's and Miss Manger's corners at once. The chairman reported that five arc lamps in London-street and three in High-street could be removed, and it was resolved that five arc lamps be extended up London-road as far as they would go, and that two lamps be erected in Eden-street and one in Portsmouth-road. Resolved, that the Council be recommended to draw a cheque for £100 to the borough surveyor, on account of commission, etc., in connection with the erection of the electric lighting works. The borough surveyor was directed to put in the concrete foundations for the new engine and dynamo. The minutes were approved of.

Salisbury.—The General Purposes Committee of the Town Council reported that at a meeting on July 9 the town clerk informed them that he had, by direction of the Mayor, communicated with Mr. R. Hammond, London, consulting electrical engineer, with respect to his consenting generally to advise the Council on the various matters dealt with in the license sought for by the Salisbury Electric Light and Supply Company, Limited, for the inclusive fee of £50 He read letters connected with the matter, and the committee resolved that Mr. Hammond should be engaged. The town clerk was directed to inform him of the engagement, and to forward to him a copy of the proposed license, with a request that he would peruse the same and then make an appointment for a meeting with the committee to discuss the matter. The committee further reported that at a meeting on July 18 Mr. Hammond attended and discussed various matters connected with the application, and they resolved that he should be requested to prepare a written report for personal submission at a committee meeting of the Sanitary Authority. The report was adopted.

Bowness.—The Local Board have received a notice from the Windermere and District Electricity Supply Company to apply for a provisional order to supply electricity for lighting purposes in the district. The Clerk stated that if the Board gave its sanction, it would be tying its hands; though, on the other hand, if a company supplied the district, the Board would have a certain amount of power, and could take proceedings if the work was not done to its satisfaction. He would suggest that the Board should not give its sanction without an equivalent. It was a new company, though it might perhaps be composed of the same people that they were already acquainted with. If the Board sanctioned the application without an equivalent, it would leave itself in their hands The Chairman took it that the position was practically this, that if anyone wished to have electric light introduced into a dwelling in Bowness, he would simply have to come to the Local Board and asked permission to break up the road to the necessary extent, and the Board would grant it. Mr. Harrison proposed that sanction be withheld until they saw what others were doing, which was seconded by Mr. Westlake, and carried.

"Medical Battery" Company.—Messrs. John H. Lile, A. L. Poulter, and L. J. Greenberg, creditor members of the committee of inspection of the "Medical Battery" Company, Limited (in liquidation), have issued the following circular: "We are glad to inform you that the Court has sanctioned a scheme of arrangement for the reconstruction of this Company. The scheme provides, amongst other things, that the new company shall issue to the creditors of the old company fully-paid 7 per cent. preference shares of £1 each to the amount of their debts, and also for the issue by the new company of first mortgage debentures of £10 each to the amount of £3,000 charged on all the property and assets of the Company whatsoever, bearing interest at the rate of £10 per cent. per annum, payable half yearly, and repayable as to principal by yearly drawings of £500, the present debenture-holders postponing their security. The furniture, fixtures, electrical plant (including statical and other appliances). 'Zander Mechanical Exercises,' etc, at 52, Oxford street, and 3, Rathbone-place (exclusive of patents, leases, and goodwill), have recently been valued by Messrs. Baker and Son, of 11, Queen Victoria-street, E.C., to realise at sale by auction £5,405."

Birkenhead.—The Finance Committee of the Town Council recommended the acceptance of plans prepared by Mr. J. N. Shoolbred for the erection of the central electrical generating station, and that the town clerk submit them to the Local Government Board. Alderman Deakin moved, and Mr. Gostenhofer seconded, the adoption of the minutes. Mr. Cook asked if the Council would be committed to all the details of the plans if the resolution were passed, or if they would come up for further consideration at some subsequent period. He had only had the opportunity of looking them over that day, but the inspection he had had did not lead him to think that they were the best adapted for the purpose. He suggested that a little time be allowed the Council to consider the plans. He would have to vote against them if that course were not adopted. Mr. Gostenhofer said it was rather difficult to know what course one was to pursue if plans in all cases were to be left open for reconsideration at the suggestion of any gentleman who did not like them. However, he did not know the public service would suffer very much if the confirmation of the plans were delayed. Alderman Deakin said the committee were in no hurry whatever, and on their behalf he agreed to postpone the consideration of the plans till next Council meeting. The minutes were then confirmed subject to that understanding.

Wrexham.—The Town Council have received a letter from Messrs. Lewis and Son, solicitors to the Electric Supply Company, Limited, stating that, for the information of the Board of Trade, they now asked whether to facilitate matters the local authority would promote a fresh provisional order. The Board of Trade sent down for the observation of the Council the following letter they had sent to Messrs. Lewis and Son: "In reply to your letter of the 30th ult., enclosing a memorial of the undertakers under the above-mentioned order and the Corporation of Wrexham praying the Board of Trade to authorise the transfer of the rights and powers of the undertakers under the order to the Corporation, I am directed by the Board of Trade to inform you that as the undertakers have not constructed any works under the order, they do not appear to possess any undertaking which in the opinion of the Board of Trade, as at present advised, could properly be purchased by the Corporation. I am further to state that the order does not appear to provide for the acquisition by the Corporation of the undertaking authorised by the order before the expiration of the time prescribed by section 2 of the Electric Lighting Act, 1888—viz., 42 years from the date of the commencement of the order. I am to add that if the Corporation desire to obtain statutory powers to supply electrical energy within their district, the Board of Trade will be prepared to consider the expediency of revoking the company's order, and granting a fresh order to the Corporation.—I am, etc., Francis J. S. Hopwood." The Town Council decided to agree to an extension of six months.

Folkestone.—The Town Council have had under consideration the scheme, outlay, and arrangements to be proposed by Mr. Daniel Baker, and matters incidental thereto, in relation to the adoption of the electric light. Mr. Baker was not present. Councillor Tolputt moved that it be adjourned for a month. The Town Clerk stated that Mr. Baker himself said he would be perfectly ready if that meeting was adjourned as usual for a fortnight. It was said in reply that there would be no adjournment. Councillor Thompson made some very strong remarks on the conduct of Mr. Baker. He said he had to draw the attention of the Council to this fact, that Mr. Councillor Baker, in that chamber and elsewhere, stated publicly that he had a scheme ready, all prepared and drawn up, under consultation with an engineer, to submit to the Corporation, but he could not bring it forward till the scheme of the Electric Lighting Committee was withdrawn. He said, moreover, that as soon as the Electric Lighting Committee's report was withdrawn he would produce his scheme. Were they, he asked, going to have that original report treated with any further contempt? If they went on in that way they would see that a company would apply for a provisional

Digitized by Google

order, and they would get it. Councillor Pursey thought the best course would be to restore the report on the agenda for next month. They ought to make an effort to let the public see that it was wrecked by Mr. Baker and other gentlemen. After considerable discussion, it was resolved, on the motion of Councillor Payer, seconded by Councillor Tolputt, that both matters be placed on the agenda paper for September.

Dewsbury.—The buildings of the Corporation electric lighting station are now almost completed. The station occupies part of the site of the old gasworks in Bradford-road, and is bounded on the east by Bradford-road, on the north by Mill-street and the beck, by the beck again and another thoroughfare, while on the south are buildings belonging to the Corporation, and at present let for other purposes. The principal structure occupies a site behind the old gas offices. This building is one externally of six bays, and is lighted from the roof, also on the east side, by circular-headed windows, and by windows with square heads at the north end. The structure is divided by a wall running from north to south, which thus forms two large rooms, one the engine-house and the other the boiler-house. The interior walls of the former, with the exception of the southern gable, are constructed of white glazed bricks, and that would have been similarly built had not the committee been of opinion that large as the structure is it may require extension, and such could only be done on the south side. In the engine-house there are to be two engines one of 200 h.p. and the other of 100 h p., made by Messrs. Willans and Robinson. The dynamos are being made by Messrs. Crompton, of London, if not already constructed, and are to occupy a place near the north end of the engine-house, and close to the switchboard. Further north, but still within the building, is the battery-room. Above the room a tank is placed, and below it is the condenser-room. The octagonal chimney is at the north-west end of the main building, and will be 126ft. high. Passing through a doorway in the west wall of the engine-house, the boiler-house is reached. There are three boilers, each 28ft. long by 7ft. in diameter, made by Messrs. J. and J. Horsfield, of Dewsbury. Each is being fitted with a mechanical stoker, by Messrs. Bell Bros., of Manchester, and adjoining is to be an economiser, by Messrs. Green. To work the stokers, two small engines are to be put down. Mr. Preece has designed the installation and advised the Corporation generally, and Mr. A. K. Greener, A.I.E.E., is acting for that body as superintendent of the electric lighting works. Mr. Marks, C.E., the borough surveyor, has designed the building, and Mr. Thomas Kelly is the clerk of works.

PROVISIONAL PATENTS, 1894.

JULY 30.

14570. **An automatic electric contact.** George Hussey, 14, Turner-street, Clitheroe, Lancs.

14580. **Continuous electric brakes for railway trains.** Alexander Young, 2, Merchiston Bank-terrace, Edinburgh.

14602. **Improvements in controlling apparatus for electro-motors.** Jean Baptiste Gustave Adolphe Canet and André Hillairet, 46, Lincoln's-inn-fields, London. (Complete specification.)

14607. **Improvements in electric cable traction apparatus.** Richard Lamb, 53, Chancery-lane, London.

14614. **Improvements in electric-magnetic motors.** Arthur Hopkins Beard, 43, Chancery-lane, London.

JULY 31.

14634. **Galvanic battery.** Charles Edward Buell, 62, St. Vincent-street, Glasgow. (Complete specification.)

14642. **Electrical battery.** Victor Isidore Feeny, 60, Queen Victoria-street, London. (Fred Dubero and Peter Mohrdieck, United States.) (Complete specification.)

14651. **Improvements in electrical heating devices.** George Cecil Dymond, 6, Lord-street, Liverpool. (Joseph Arthur G. Trudeau, Canada). (Complete specification.)

14689. **Improvements in secondary batteries.** Francis Tallack, Francis William Tallack, and Louis Héndlé, 10, Great Turnstile, Holborn, London.

AUGUST 1.

14765. **Improvements in apparatus for electrically effecting the reproduction at a distance of graphic matter or designs written, printed, stencilled, photographed, or otherwise produced.** Rupert Greville-Williams, 22, Southampton-buildings, Chancery-lane, London.

14768. **Improvements in electric arc lamps.** Alfred Lyster Shepard, 8, West Kensington-gardens, London.

14769. **Improvements in or relating to apparatus for the production of sulphuric acid by the aid of an electric current.** Richard William Hill, 54, Fleet-street, London.

AUGUST 2.

14841. **An improved diaphragm for phonographs and similar sound-recording and sound-producing machines.** Walter Edward Hunnex, 19, Morland-road, Croydon.

14847. **Improvements in the means for storing electric energy.** John Evelyn Liardet, 9, Warwick-court, Gray's-inn, London.

14858. **Improvements in the purification of saccharine juices by electrolysis.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Emile Javaux, Charles François Gallois, and François Dupont, France.)

14850. **Improvements in the manufacture and production of filaments or incandescing media for electric lamps.** Rudolf Langhans, 47, Lincoln's-inn-fields, London.

14859. **Improvements in or connected with means for the supply or distribution of electricity.** William Godson Little and Charles William Godson Little, 47, Lincoln's-inn-fields London.

AUGUST 3.

14922. **Electrically-worked apparatus for regulating signals.** Wilhelm Fiedler, 67, Chancery-lane, London. (Complete specification.)

14926. **Improvements in electric telegraph and signalling apparatus.** Frederick Thomas Hollins, Saltley House, Forest Drive, Leytonstone, London.

AUGUST 4.

14988. **An electrolytic table.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Ernest Solvay, Belgium.)

15000. **An improved wind motor for driving electric machinery and other purposes.** Honoré Soifranc, 18, Buckingham-street, Strand, London.

15004. **Improvements in telephone installation.** George Ritter, 76, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

13533 **Clip for extracting and replacing electric fuses.** Hutchins.

14056. **Electrolytes for primary batteries.** Longsdorf.

18911. **Electrical contact apparatus worked by passage of railway trains.** Tyer.

18912. **Electrical railway signalling apparatus.** Tyer.

23170. **Electrical transformers.** Miller and Woods.

1894.

8061. **Electro-chemical decompositions.** Carmichael.

8086. **Electric alarm for pressure gauges.** Bradt.

10658. **Electric bells.** Goldby. (Neumann.)

10659. **Suspending incandescent electric lamps.** Goldby. (Neumann.)

11418. **Telephone transmitters.** Kingsbury. (Western Electric Company.)

NOTES.

Market-Lighting.—The new market at Pontypool is to be lighted by electricity.

New Cable.—The Ceylon authorities have decided to lay a new cable to India *viâ* Paumben and Talumannar.

Dynamos in Russia.—It appears from a Russian contemporary that the construction of dynamos is not yet carried out on a large scale, and that those made are extremely high priced.

Burma and China.—It is stated that the construction of the telegraph line between Burma and China is being carried out under the superintendence of a European official in the employ of the Chinese Government.

Electrical Trade Section.—At a meeting of the Electrical Trade Section of the London Chamber of Commerce held on Tuesday last, Mr. E. Garcke presiding, Mr. Sydney Morse was unanimously elected a vice-chairman of the section.

Crystal Palace School of Engineering.—There was a large gathering last week of the friends and students belonging to the Crystal Palace School of Practical Engineering on the occasion of the distribution of the certificates gained during the summer term.

Overhead Travellers.—In connection with the extension of the West India Dock, which was opened yesterday, overhead travellers worked by electric motors have been installed for the purpose of manipulating timber in large logs. The results have been eminently satisfactory.

Carborundum.—The production of this material, to which we have referred on previous occasions, has been undertaken at Benatek, in Austria-Hungary. The results have been so successful that it has been decided by the Landerbank of Vienna to establish large works in Austria and in France.

The Century of Electricity.—M. L. Mascart, in the course of his presidential address delivered last week before the Association Française pour l'Avancement des Sciences in congress at Caen, remarked that whatever our successors may witness, we are able to say that the nineteenth century will be justly called the century of electricity.

Electric Traction in Germany.—Approval has been given to the construction of an electric tramway from the Pillau railway station to Augusta-strasse, Königsberg. The Municipality of Altendorf, near Essen, have sanctioned a proposal for an electric tramway to Essen-Frohnhausen, and its extension to Heissen and Mülheim-on-the-Ruhr.

Obituary.—The death has just occurred, at the age of eighty-one, of Mr. Charles Liddell, a well-known railway engineer. The deceased, as a partner in the firm of R. S. Newall and Co., at one time took an active part in the laying of telegraph cables. During the war in the Crimea it is reported that he laid the cable between Varna and Balaclava.

Electrical Exhibition at Worcester.—An exhibition of electrical appliances is to be held in the Public Hall at Worcester in October, on the occasion of the opening of the Corporation electric lighting works. Those who are desirous of exhibiting are requested to communicate with Mr. F. R. Davenport, secretary, Electrical Exhibition, Guildhall, Worcester.

Lighting at Seville.—A company has been registered in Seville under the title of the Sociedad Sevillana de Electricidad, with a capital of £80,000. The company propose to commence the laying of cables at the end of September or beginning of October, and it is expected that such progress will be made with the installation that it will be possible to supply the electric light at the end of May of next year.

Overhead Copper Wires.—The subject of the strain upon overhead copper wires, and the influence of temperature upon them, is discussed by Mr. Josef Herzog, of Budapest, in the *Elektrotechnische Zeitschrift* of the 9th inst. The author deals mainly with telegraph and telephone wires, and gives a graphic representation showing how to ascertain the strain for given wires over given distances and at different temperatures.

Electric Lighting in Switzerland.—The Rathausen supply station, Lucerne, will be now carried out, a Zurich banking firm having provided the necessary money. The Lucerne Municipality intend to buy the central station at Thorenberg belonging to Messrs. Troller Bros. and Co., which furnishes current to all the present private consumers and part of the public lighting. This station, of about 600 h.p., is, however, not large enough, and the town will erect a second station.

Canal-Lighting.—The great advantage of the electric light in the saving of money and time is illustrated in a return just made of the average time occupied by ships passing through the Suez Canal. With the electric light, the journey is accomplished in eight minutes under 20 hours. Without the light, 31 hours and 24 minutes are required. The percentage of ships using the electric light steadily increases. In 1892 it was 83 per cent. Last year only eight ships out of a hundred dispensed with its use.

Gas and Electricity at Newport (Mon.).—The chairman of the Newport Gas Company (Mr. E. J. Phillips) remarked at a meeting of the company on Monday that it was possible that the electric light installation which the Corporation were about to make would affect the company to some extent, but that the electric light could not be produced to compete with them. It would, he thought, be a luxury to those who wished to use it. Evidently Mr. Phillips has not made himself acquainted with the progress made in electric lighting.

Rope versus Belt Driving.—With a view to deciding the comparative merits of rope-driven and belt-driven plant, the Société Industrielle du Nord de la France instituted a series of experiments to determine the power absorbed in transmission by ropes and by belts. These trials were made last week at the works of M. Dujardin, a compound steam-engine of 200 h.p. driving a dynamo capable of energising up to 1,400 incandescent lamps being used for the purpose. *L'Industrie Electrique*, from which this item is taken, states that it will publish the results of the trials on a future occasion.

Gas and Electricity.—At Wednesbury complaints have been made at a meeting of the Wednesbury Town Council that the quality of the gas supplied is very bad, and one alderman testified to it being sometimes so poor that he had to use a candle. Mr. Griffiths, of the Gas and Water Committee of the Council, mentioned that the question of adopting a system of electric lighting had engaged their attention, but it was, he feared, too big an order to be entertained just now. Under the circumstances, however, we should say that the sooner Wednesbury gets the electric light introduced, the better it will be for the comfort of the inhabitants.

And So Say All of Us.—The report just issued by the North-Eastern Sanitary Association for the year 1893-94 contains the following note concerning the electric light: "The *pros* and *cons.* relating to this subject, as regards the home, were fully stated in last year's report. Con-

Digitized by Google

trasted with all other illuminants it is wholly beneficent—it is purity *v.* foulness in air food. It should therefore be adopted by all who possibly can do so, and it pays so to do. Class it as a primary and you must gain by the exchange whatever sacrifice may be necessary to secure it—gain in health, in mental vigour, which inevitably suffer from breathing air vitiated by gas, etc."

The New Blackwall Entrance Lock.—This lock was opened yesterday. A large party proceeded to Brunswick Pier, embarked upon a steamer, and steamed to the entrance lock. The party then entered the lock and disembarked. The chairman of the London and India Docks Joint Committee opened the middle gates, and after inspection of machinery the party re-embarked, and the steamer proceeded through the lock, cutting the ribbon just across the centre. The party next steamed through the cut into the import dock to the west end, landed on the north quay, and worked their way up to the West India Dock Station, returning by train to Fenchurch-street.

Automatic Telephone Exchanges.—In our issue of the 15th June last our correspondent briefly referred to the Nissl automatic telephone exchange system, which was decribed by Mr. F. Ross before the second annual meeting of the Union of German Electrical Engineers at Leipsic. Those who are desirous of learning the details of the method will find an illustrated description of it in the *Elektrotechnische Zeitschrift* of the 9th August, and a similar account in the New York *Electrical Review* of the 1st August. It will be remembered that the principle of the system lies in the use of a single wire for several subscribers to an exchange, but the method has not yet been practically employed.

Electric Lighting in Germany. — In connection with the central electricity station to be erected in Dresden the Municipality intend to keep the plant for lighting purposes separate from that for the supply of power to the electric tramways. The power station in Pfotenhauerstrasse will be extended, and will furnish current to the Blasewitz line of the Deutsche Strassenbahn Gesellschaft. At Steinau-on-the-Oder good progress is being made in connection with the central station; it is expected to be ready by October. The demand for current from the central station at Altwasser, which is owned by Herr Wunder, has largely increased, and the installation is to be extended in consequence.

"Dynamo Attendants and their Dynamos."—Under the title of "Dynamo Attendants and their Dynamos" Mr. Sidney Rentell, of 29, Ludgate-hill, E.C., has published in book form, at the price of 1s., a series of articles which originally appeared in the columns of our contemporary *Electricity* from the pen of Mr. Alfred H. Gibbings, A.I.E.E., electrical engineer to the Corporation of Hull. The booklet is divided into 10 chapters, dealing with the dynamo-room, the dynamo, the dynamo as designed for different purposes, causes and prevention of sparking, principal causes of failure of action, faults, repairs, instruments, compound circuits and dynamo coupling, and economical work. The work should be useful to those attending to dynamos both in private installations and in central stations.

Mysterious Action of Alternating Currents.—An eminent consulting electrical engineer brought an extraordinary case of the mysterious action of alternating currents before Section G of the British Association. Alternating leads were carried into Mappin and Webb's through separate iron pipes, and the consulting electrical engineers were astounded to find there was a drop. After investigation it was found that the iron pipes had some mysterious action. Another case came to our knowledge some years ago. A house was installed with two thick mains with lamps across. The mains were also joined at the far end. It was found that when the dynamo was coupled on there was always a short-circuit. After careful investigation by several consulting engineers it was found that when the leads were separated at the far end things went better.

The "Submarine Sentry."—A correspondent writes to the *Times* as follows: "Notice has been given that, owing to the outbreak of war between China and Japan, lights on the Formosa coast have been extinguished, and no doubt others, both in Japan and China, will also be put out, or false lights substituted, to suit the purpose of either. Under the circumstances it will be necessary for all steamers navigating these waters to be extra careful, and I would suggest that one of the best precautions is to use the 'submarine sentry,' as with its use in nearly every instance a vessel going at 10 knots can be assured that she has at least 20 fathoms of water under her keel, and warning given on board if less depth is reached, thus giving ample time for position to be verified." It will be remembered that the "submarine sentry" is an electrical arrangement devised for giving the warning mentioned.

Electric Traction in Hungary.—It is proposed to construct an electric tramway from Budapest *viâ* Uj-Pest (Newpest) to Rakos-Palota, and the matter is now under the consideration of the Minister of Commerce. At Pressburg an electric line is about to be built both for goods and passenger traffic. With regard to the projected underground electric railway in Budapest, to which we have occasionally referred, it now appears that the Minister of Commerce has approved the principle of the line. In this connection a telegram from Vienna on Monday last states that the Hungarian Minister of Commerce has granted a concession for the construction of an underground electric railway in Pest. This line will be two English miles in length, and will pass from Giselaplatz to the Thiergarten. It will be the first electric underground railway in continental Europe. It is to be opened on April 1, 1896.

New Electric Locomotives.—It is stated that the Compagnie des Chemins de Fer de l'Ouest, as a result of the experiments made with the Heilmann locomotive, have just ordered two new locomotives from the Société de Traction Electrique, who, it will be remembered, work the Heilmann patents. Certain improvements and modifications suggested by the trials of the original engine will be embodied in the new locomotives with a view to the construction of a definite type. The steam-engine chosen as best fulfilling the working conditions is the Willans. It is further stated that Messrs. Willans and Robinson, through their French agent, M. A. H. Crozier, have been commissioned to deliver by January or February next two steam-engines, each of 1,500 h.p. It is intended to conduct experiments with the new locomotives in May, 1895, and if the results are conclusive it is reported that the Heilmann locomotive will be definitely adopted.

Search-Lights on War Vessels.—It appears that search-lights were indiscriminately used during the naval manœuvres, the result of which in the case of actual war would probably be disastrous to vessels belonging to the same nation. For instance, the night alarm early on the 6th inst. at Belfast, when the Red squadron imagined that they were being attacked by Blue torpedo boats, shows the danger there would be in war time of friendly ships firing into each other amidst the confusion of a night attack, and also the necessity for greater discretion in the use of electric search-lights. A search-light properly handled may be

Digitized by Google

found of great assistance, but the reckless and indiscriminate flashing of these lights in every direction by every ship of the squadron attacked only has the effect of blinding and dazzling the officers and men in the threatened ships, and of giving additional security as well as a brilliantly illuminated target to the attacking torpedo boats.

Train-Lighting.—With reference to the editorial comments on this subject in our last issue, it is to be regretted that the Midland Railway Company have decided to abolish the use of the electric light on their trains. Mr. G. E. Paget, the chairman of the company, made an official announcement to this effect at a meeting of the company on Friday last. He stated that it was to him a source of great disappointment when this had to take place, for the light was a beautiful one. Unfortunately, he remarked, it was very costly and not sufficiently reliable, and they had been obliged to adopt a fresh system. They had not yet arrived at the perfection of train-lighting, but he thought they would agree with him that oil-gas was an exceedingly good light, and better in every respect than oil lamps. So it is, but it is a most unfortunate step to renounce the electric light, which is still better than gas. The Midland Company have always considered the comfort of their passengers, but on this question of illumination, and after the above decision, they can hardly be considered to be doing so in this respect.

Electric Traction in Switzerland.—An electric tramway has been projected for a long time at Basle, and arrangements have now been made by the Municipality with Messrs. Siemens and Halske, of Berlin, and Messrs. R. Alioth, of Basle-Mönchenstein, to carry out the work. The town will pay the cost of construction, but the two companies concerned will work the line for two years. The overhead system is to be adopted. The first section to be constructed will connect the Badisch railway station with the Central railway station, will pass over the old Rhine bridge, and through the busiest street of Basle-Stadt and Basle-Dorf. The line will be about two miles in length, and for the most part will have a double track. The gradients are as high as 1 in 20. It is proposed to have 12 motor cars, with which a three-minutes' service will be maintained. It is expected that the line will be opened for traffic by next spring.—Some months ago we referred to the proposal brought forward to construct an electric tramway in Fribourg. A committee appointed to consider the subject has now issued its report, from which it appears that the scheme is progressing satisfactorily.

Lighting of the Houses of Parliament.—In the House of Commons a few days ago Mr. H. Gladstone, in reply to a question, stated that the matter of providing the Houses of Parliament with an electric light installation had already received careful consideration. The evidence before him showed that no complete installation of electric lighting machinery and plant could be established within the building without occasional serious interference with its proper ventilation, and they had already some experience with a partial installation which confirmed that view. The generation of electricity within the building had been abandoned both for this reason and because the boilers now existing were no longer strong enough to bear the strain of working both the ventilation and lighting systems. The cost of constructing a complete electric station outside the building in connection with the warming and ventilating arrangements had been considered, and it would probably reach £30,000 or £40,000; while the expense of wages and maintenance would also be very heavy. The subject would receive further attention, but, having regard to all the circumstances of the case, it must be deferred for the present. Taking into account the capital outlay, he was not at all prepared to admit that the saving would be any thing like that suggested.

Electric Lighting at Geelong.—According to the *Melbourne Argus* of July 18, under the heading of Geelong, "efforts have been made by the municipalities to obtain the introduction of the electric light to the streets of the town and suburbs, and matters have so far progressed that the question has now only to be decided by the individual councils interested. Last night a conference of the representatives of the Geelong Town and the Newton and Chilwell and Geelong West Borough Councils was held in the Town Hall in Little Malop street. It was held for the purpose of adopting or rejecting certain recommendations made by a sub-committee from the conference. These, in effect were that the conference should accept the offer of the Crompton Electric Supply Company to give a complete electric installation for the sum of £15,150. Considerable opposition was manifested, many of the councillors present being of opinion that tenders should be called for the electric light service, but the resolution to adopt the sub-committee's recommendation was carried by 12 votes to 8. The next stage in connection with the question is to acquaint the different councils with the determination of the conference, and they will be asked to give effect to the resolution carried adopting the sub-committee's recommendation for the acceptance of the offer of the Crompton Company."

Electrical Measuring Instruments.—A handy price-list of electrical measuring instruments has reached us from Messrs. Nalder and Harrison, of Trafalgar House, Great Newport-street, W.C. The instruments constructed by the firm are the result of several years' practical testing and supervision of all classes of electrical instruments, and the improvements suggested by that experience have been embodied in the types which are illustrated in this list. There are two classes of instruments. The first, or standard type, is claimed to be absolutely free from the errors inseparable from even the best type of meter containing iron; the second comprises those containing iron, and which are made so that an accuracy sufficient for all practical purposes can be guaranteed. The ammeters, which are for alternating and direct current, range in capacity from 20 to 300 amperes. The magnetic movement actuating the pointer is designed according to the Harrison patents, a combination which reduces to a minimum the error due to hysteresis, and at the same time allows of any type of scale being obtained. The voltmeters are similar in action to the ammeters, and they are made in both the gravity and marine types. Among other instruments mentioned in the list is a recording voltmeter for direct current, and which is constructed so sensitive as to record a variation of less than 0·3 per cent. A recording ammeter for alternating or direct current is also referred to, the object being to obtain the maximum amount of force moving the registering pen with the minimum consumption of electrical energy. This object has been attained by an arrangement of the magnetic field which concentrates the force of the movement actuating the recording pen. The remainder of the price-list is devoted to portable testing sets, standard voltmeters and wattmeters, and standard ammeters, switchboards, switches, etc.

Commercial Efficiency of Accumulators.—In *L'Industrie Electrique* of August 10, M. Hospitalier publishes some particulars of the commercial efficiency of accumulators obtained during the present year. These batteries, which are of the Laurent-Cély type, are used by the Paris company having lighting powers in the Place Clichy district, and whose central station is situated in the Rue des

Digitized by Google

Dames. There are two batteries installed, each consisting of 250 cells. Each cell contains 23 plates suspended from their upper ends; the positive plates are 8mm. and the negative plates 6mm. in thickness, and the total weight of a cell is 3cwt. The working conditions of the cells are as follow:

	Discharge in amperes.	Capacity in ampere-hours.
Normal	250	2,000
Strong	340	1,700
Maximum	450	1,350

During the working of the generating plant, the power not required for lighting is used for charging the batteries. To obtain at the battery terminals the difference of potential necessary for the total charge, a supplementary dynamo, termed a pressure raiser, is added in series with the large lighting dynamos. The two batteries meet the whole of the requirements of the district during the stoppage of the machinery; they can be connected in quantity in case the discharge becomes too intense for one to deal with. This operation frequently takes place from midnight to about 1 a.m. The batteries are used on alternate days. The writer then gives a tabular statement of the discharge and charge during the first five months of the current year. It appears from the figures that the energy efficiency amounted to 65·5 per cent. in January, 67·9 in February, 70 in March, 69 9 in April, and 71·8 per cent. in May, being an average efficiency of 69 per cent.

Formation of Floating Metallic Films by Electrolysis.—In the *Ann. Phys. Chem.*, Messrs. F. Mylius and O. Fromm deal with this subject. It appears that during the electrolysis of a concentrated zinc sulphate solution, it was observed that the cathode wire became surrounded by a film of metallic zinc floating upon the surface of the solution, the film increasing gradually to a considerable size. A somewhat similar observation has been made by F. Kohlrausch in the case of the electrolysis of a solution of silver chloride in ammonia, and the authors have therefore been led to study the conditions under which the formation of such films takes place. Experiments made with zinc sulphate and ammoniacal silver chloride show that the two principal necessary conditions are an impure state of the surface of the solution, and the presence of oxygen in the atmosphere above the solution. If the surface is perfectly clean formation of a film is not observed, whilst, on the other hand, the addition of the smallest trace of any oily impurity, such as turpentine, which will float upon the surface, favours the film formation. If the air above the liquid is replaced by hydrogen, carbonic anhydride, or nitrogen, the film is not formed. Observations with both the zinc and silver films point to the presence of some trace of oxidised metal in the film, and if the surface of the solution is covered with an oil that has been completely freed from dissolved oxygen the film is not formed. In other cases the formation of a film below the surface of the liquid, as at the boundary between the solution and a heavy oil-like chloroform, is possible. Films were also obtained from copper, cadmium, cobalt, iron, and antimony solutions. When the copper solution is treated with a solution of sulphur in a mixture of benzene and carbon bisulphide, the surface film consists chiefly of cuprous sulphide, and a solution of iodine in benzene on the surface of silver sulphate gives rise to the formation of a silver iodide film.

Alabaster and Others v. Harness.—Judgment was given in this action last week by Mr. Justice Hawkins in the Queen's Bench Division. The plaintiffs are the proprietors of the *Electrical Review*, and the defendant, Mr C. B. Harness, was the manager of the "Medical Battery Company. The plaintiffs were successful in an action brought against them by Dr. Tibbits for alleged libel, but they were unable to recover their costs, and they now sued Mr. Harness, alleging that he was really maintaining the plaintiff in the action. Mr. Justice Hawkins, in giving his decision, said, after the judgment of Lord Chief Justice Coleridge in Bradlaugh *v.* Newdigate, he need not take very much time over the present matter. The counsel for Mr. Harness, Mr. Jelf, did not deny that the defendant did maintain Dr. Tibbits, but contended that the defendant believed he had a common interest. Whether that were so or not was the point. His lordship had to determine the question, What was improper maintenance? The principle was laid down that it was maintenance of a party in a suit where the maintainer was not concerned. An exception was made in the case of aid given out of charity to a poor man. It could not be suggested that the support of Mr. Harness was due to a neighbourly action or to a charitable impulse. The point simply was had he, or did he believe he had, a common interest with Dr. Tibbits in the matter at variance. No doubt the article complained of by Dr. Tibbits attacked Mr. Harness also, but the comments on Mr. Harness and his belts did not make such a common interest in the suit as to justify maintenance. In no proper sense could a libel on Mr. Harness be treated as the matter at variance. It might seem hard that a man could not maintain a man who, in defending his own character, had almost necessarily to defend the character of the maintainer also. Did Mr. Harness reasonably believe in such a state of things as would have justified him in maintaining Dr. Tibbits? His lordship thought not. The verdict would be entered for the plaintiffs for the costs they claimed. Judgment was given accordingly. We congratulate Messrs. Alabaster, Gatehouse, and Co. on the result of this action.

Chloride Cells for Launch Work.—An interesting application of an electric launch took place on the 11th inst., on the occasion of the Goring-on-Thames regatta, when the new electric launch, "Aphrodite," was used by the Thames Conservancy for clearing the course during the day. This boat was built at Goring in Mr. S. E. Saunders's boatyard, and has been fitted up in a very superior style. It measures 35ft over all by 5ft. 3in. beam, and although built for comfort and not for speed, the most satisfactory results have been obtained in the latter respect. The arrangement of the electrical details has been carried out by Mr. H. A. Earle, of Messrs. Mather and Platt, Limited, 16, Victoria-street, Westminster. The novel feature consists in the employment for the first time on the Thames of a battery of chloride cells, a description of which we published some time ago. These cells are manufactured in England by the Chloride Electrical Storage Syndicate, Limited, of 16, Victoria-street, E.C., and the launch has been specially built in order to demonstrate their advantages for this class of work, their large capacity for a given weight enabling distances and speed to be run which were previously impossible without recharging. The cells with which the "Aphrodite" is fitted are capable of being discharged at a very high rate, and on the measured mile a speed of nine miles per hour has been obtained, and this rate, we are informed, can be continuously maintained for about three hours, being a record performance for an electric launch of this size. At slower speeds—namely, 6½ miles per hour, which is the usual rate of travel, and which is still considerably above the average speed of electric launches of this size—a day's run of nine hours can be undertaken, inclusive of the time taken through locks. One feature of the chloride cells is that although at very high rates of discharge their

Digitized by Google

capacity for a given weight exceeds that of other types, their increased capacity at low rate is still proportionately greater, and on this account, with the reduced speed of 5½ miles per hour, the battery power with which this launch is provided is said to be capable of covering a distance of approximately 110 miles without recharging.

The Kiew Electric Tramway.—Although some time has elapsed since the construction and setting in operation took place of the electric tramway at Kiew in Russia, the first line of its kind in that country, some information concerning its principal features, more especially as the generating plant is driven by gas-engines, should prove interesting. The tramway commences at the Alexandrowski Place and connects the Padol, the commercial part of the town, with Krestchatique, the principal street of the holy city. The line is about two miles long, with gradients as high as 9·3 per cent. The generating station is situated about half-way between the termini, and as the tramway is a single line, turn-outs have been provided at various points. The station contains two direct-current bipolar dynamos, each having an output of 30 kilowatts. At a speed of 900 revolutions a minute each generator gives 30 amperes at 500 volts, and it is possible to overload them to the extent of 30 per cent. without abnormal heating. These machines, which were constructed by the Allgemeine Elektricitäts-Gesellschaft of Berlin, are each belt driven by an Otto two-cylinder gas-engine of 60 h.p., fitted with a double flywheel and running at 140 revolutions. There is also installed a 2-h.p. gas-engine, which is employed for starting the two large motors. The arrangement adopted for this purpose deserves notice. The small engine drives by belt a countershaft arranged under the floor of the station. This shaft carries two pulleys, which transmit a rotary movement by means of belts to two other pulleys, on the axes of which is arranged a friction cylinder. By means of a lever this cylinder is pressed strongly against the face of the flywheel and forces the latter to turn. This arrangement allows of the motors being started easily and rapidly. The gas required for the engines is obtained from the local gasworks; it is a mixture of coal-gas and of gas derived from the distillation of naphtha residuum. This mixture is good for illuminating purposes, but is not so suitable for gas-engines as is ordinary gas, consequently it has to be used at a higher pressure. The working of this tramway has been very satisfactory, and, as stated in a previous issue, extensions are shortly to be made.

Transmitting Pictures by Electricity.—One of the most interesting subjects before scientific societies at the present time is the problem of transmitting images to a distance by electricity. In this connection Mr. C. Francis Jenkins, in the New York *Electrical Engineer*, offers for what it is worth a theoretical device which may be added to the methods already suggested for the accomplishment of this object. His scheme contemplates the use of selenium for a receiver, and the apparatus is substantially as follows: A rectangular or circular non-conducting plate is set up behind a lens in such a manner as to receive the image or scene to be transmitted. This plate or board has upon its back a number of small short wires of selenium or sulphur, one end of each of which is thrust through the non-conducting board and immediately turned back, coming out again upon the same side and very near where it was thrust through. The face of the board is covered with these little loops, one end of each of which is joined to a common conductor, the other ends having separate conductors extending over the distance intervening between the transmitting and receiving stations. At the receiving end is a large flat electric lamp of ground glass with filaments in number and position corresponding with the loops at the transmitting station—a filament for each loop and in circuit with it. We now have a number of selenium loops, each upon a separate circuit, which are affected by the light passing through the lens at the transmitting station, and in circuit with these loops, filaments in a lamp common to all the circuits. As the conductivity of each circuit is affected by the light impinging upon the selenium loop at the transmitting station, each circuit carries a different quantity of the electric current generated by a dynamo in the wire common to all the circuits. The result is that all of these little filaments glow, but each with a different intensity, and the light diffused over the flat surface of the ground-glass lamp at the receiving station appears brighter in some parts than in others, the bright parts corresponding in position to the bright parts of the image projected upon the board by the lens at the receiving station. The scheme, if practicable when necessary modifications are made, is objectionable in that it contemplates a multiplicity of conductors, but as a basis for study Mr. Jenkins considers that the method has its merits.

Economy of Incandescent Lamps.—A paper on "Incandescent Lamps: Their Use and Abuse," was read by A. D. Page at the recent meeting of the North-Western Electrical Association, St. Paul, U.S. In referring to several diagrammatic curves and a table, the author stated that in considering these curves and table it should be remembered that the result would have been much less favourable to the higher-economy lamps had the test been made and the curves plotted with poorer quality of lamp, and also that satisfactory results with lamps of higher economy than 3½ watts per candle can only be obtained by exercising the greatest care in maintaining a constant voltage at the lamps. The table demonstrated that even at 600 hours lamps of the highest initial economy show the best average result as to average watts per candle and average candles per horse-power; and that at 900 hours three-watt lamps show better average results than lamps of 3·6 or four watts. The greatest objection which can be urged against the high-economy lamp is that while at 900 hours the four-watt lamp reaches a minimum candle-power of 13¼ candles and the 3½-watt lamp about 12 candles, the three-watt lamp reaches 10 candles, and the 2½-watt lamp at 600 hours reaches eight candles. At the present price of lamps, where fuel is high and the customers' bills are made up on the basis of lamp hours, it would, he submitted, pay the station to use high-economy lamps, breaking them at a point which would insure satisfaction as to average light and keeping the average life comparatively short. The author opined that whatever economy or make of lamp is used, by no means can the efficiency of the station be so greatly increased, as by making every possible effort in the direction of maintaining a constant voltage at the lamps. This can only be accomplished and maintained by constant use of reliable portable instruments. No switchboard instrument should be relied on without often checking it by some reliable standard, and it should also be borne in mind that, owing to the varying drop at various loads, constant voltage at the station is just what is not wanted. If a reliable portable voltmeter is not possessed, such an instrument should be the next purchase, then by constant use on the circuits at different loads, and profiting by the knowledge thus obtained, a marked improvement would soon be found in the lighting, and engineers would be in a position to judge which make and what economy of lamp is the best for them to purchase.

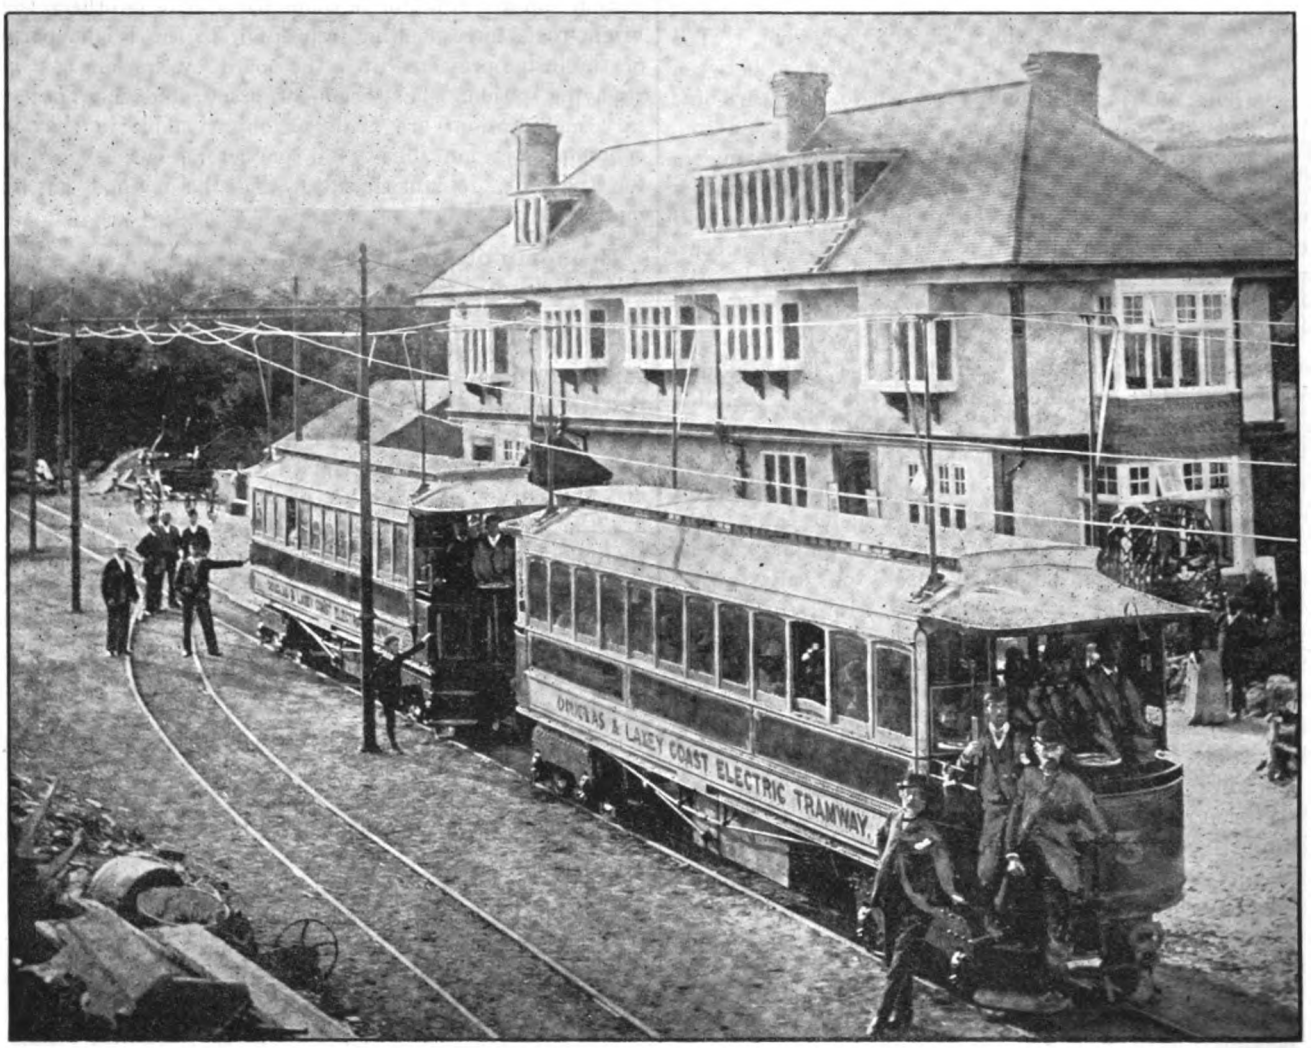
THE DOUGLAS AND LAXEY ELECTRIC TRAMWAY.

General Remarks.

The opening to public traffic of this electric tramway throughout its whole length, and to which we referred in our issues of 3rd and 10th inst., is an event of considerable importance. The line not only opens up a new and populous district which has hitherto remained in a great part excluded from the progress made by other parts of the island, but from the novel features of the work itself it will form a most interesting attraction to visitors. The line has been constructed under the Douglas and Laxey Electric Tramway Act passed by the Legislature of the Isle of Man on May 30, 1893, and promulgated by the Governor, Council, and Keys in Tynwald assembled on November 17, 1893. As mentioned in previous issues, the line was been constructed by Messrs. Mather and Platt, Limited, of the Salford Ironworks, Manchester. It was designed by Dr. Edward Hopkinson, who has also acted as consulting electrical engineer for the tramway company. Mr. Ramage and Mr. Wood have been the resident engineers for Messrs. Mather and Platt. Messrs. Galloways have been the sub-contractors for the boilers and engines, and Messrs. G. F. Milnes and Co., of Birkenhead, supplied the cars.

The tramway, of which illustrations are annexed, comprises a double line throughout; it is of 3ft. gauge, seven miles long (double)—or 14 miles in all—and extends from the end of the promenade in Douglas at Port-e-Vada to Laxey. Commencing at a point 20ft. above mean high water, the line rises in a distance of about 1½ miles to Lagbirrah, where it is 258ft. above the sea-level. It then falls to the Groudle Glen, at a height of 128ft. above sea-level, which it crosses by a fine stone bridge of three arches,



Douglas and Laxey Electric Tramway—View of Cars, Overhead Conductors, and Inn at Groudle Glen.

inspected by Colonel Rich, late chief inspector of the Board of Trade, and Major Cardew, on behalf of his Excellency the Governor, on 27th ult., and they gave their certificate the same day that the requirements of the Act and all precautions necessary for the safety of the public had been complied with. The line was accordingly opened for public traffic throughout its entire length the following day. The rapidity with which the tramway has been constructed and equipped with electrical plant is remarkable. Although involving heavy rock cuttings, several embankments, and a massive stone bridge, only seven months have been occupied in construction, a fact which reflects great credit on Mr. F. Saunderson, the engineer, and on Mr. Alex. Bruce, J.P., of Douglas, the chief promoter and chairman of the company. The contract with Messrs. Mather and Platt, Limited, was not let until the beginning of March of the present year, from which it will be understood that the electrical plant was designed, constructed, and erected in under five months. The whole of the electrical plant has

55ft. to the crown from the stream, and 130ft. in length. Rising again, the line reaches the highest point when it crosses the public road at Laxey at the Halfway House, at a height of 337ft. above sea-level. After crossing Glen Gawne at a height of 236ft., it again ascends and recrosses the public road 297ft. above the sea, and then descends to Laxey, where the terminus is just below the town, at a height of 115ft. above the sea, as shown in the section. The steepest gradient is 1 in 20, and the sharpest curve 100ft. radius.

The Power Stations.

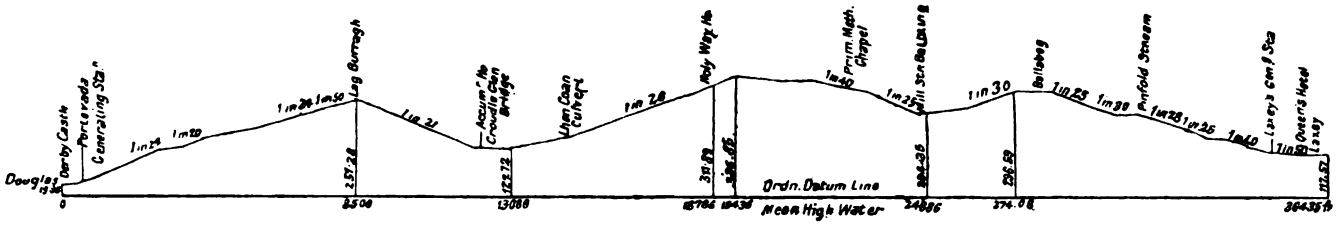
There are two power stations—one at Port-e-Vada, the Douglas terminus, and the other near the Laxey terminus. The former contains three Lancashire boilers, 20ft. long by 6ft. diameter, working at 120lb. pressure, and three compound side-by-side high-speed vertical engines, which drive by link belts with jockey pulleys two Manchester dynamos, each for an output of 100 amperes at 500 volts, and a Mather and Platt dynamo of the same output. A separate

Digitized by Google

condenser is provided for the exhaust steam, the steam-pipes are duplicated throughout, and the boilers have alternative feeds by injector and donkey pump.

The current is conveyed from the dynamos to the switch-board, which is arranged for coupling any of the dynamos to the feeder circuit or to any of the working conductors. A Kelvin electrostatic voltmeter is provided for each dynamo, and an ampere-meter for each circuit. The switchboard is also fitted with a subsidiary board for measuring the currents returning through the earth, in compliance with the requirements of the Board of Trade.

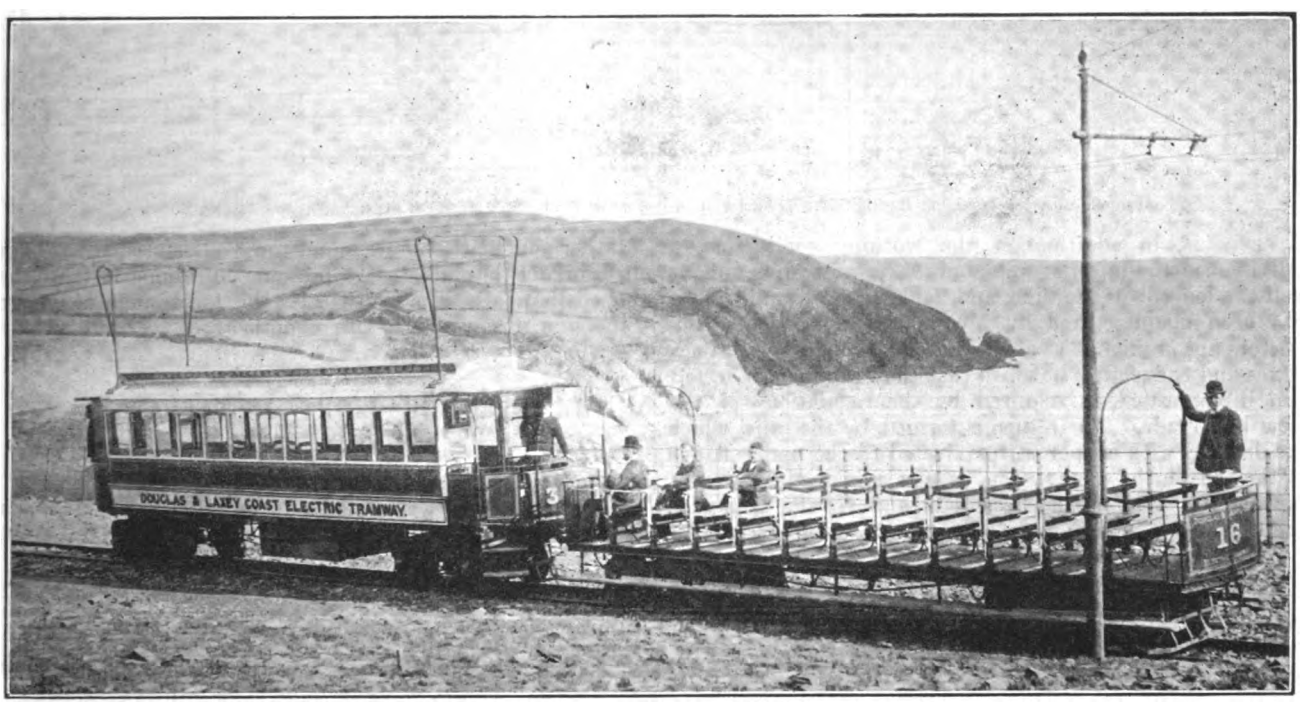
70 amperes for nine hours, and are remarkable for the exceedingly level curve E.M.F. which they maintain up to the end of discharge, and for the very high rate at which they can be discharged without detriment. Half the cells of the battery are of the Chloride Company's patent protected type, with teak separators and asbestos diaphragms, similar to those now being used on the Birmingham tramways, and the other half unprotected. The cells are charged direct from the line or from a motor generator, which is of special design by Messrs. Mather and Platt, which gives the required additional E.M.F.



Douglas and Laxey Electric Tramway—Longitudinal Section of Line.

This station, as is also the adjoining carriage shed, is lighted by incandescent lamps supplied from the power dynamos, and it likewise contains a motor-alternator of 30-kilowatt capacity, 1,000 volts, which is used for lighting some of the large hotels, theatres, and dancing saloons in the immediate neighbourhood. The power plant, in addition to providing the current for the motor-alternator, is also used for energising 20 arc lamps erected in Derby Castle, and for a distance of 1,000 yards along the roadway. The

This is the first instance of accumulators being used as a fixed battery for tramway or railway work in this country, although a similar step has been taken in the case of the Zurich-Hirslanden tramway referred to in the *Electrical Engineer* of July 20 last. The battery at Groudle Glen serves not only the function of supplying the extra power required at times of maximum demand, but it is intended during the winter months to work the light cars, which will then be sufficient for the traffic, after the close of the



Douglas and Laxey Electric Tramway—View of Motor Car and Trailer.

latter lamps are fixed on the same poles as are used for carrying the overhead conductors of the tramway. The station is arranged for the accommodation of a fourth engine and dynamo, and additional motor alternators.

The Laxey power station is similar to that at Douglas, but is equipped with only two boilers and engines of the same size, and two Mather and Platt dynamos of a similar output.

The Use of Accumulators as an Auxiliary.

One of the most noteworthy features in connection with the line is the use of accumulators. At Groudle Glen, situated 2½ miles from Douglas, a battery of 240 cells has been erected in a building specially constructed for the purpose. These cells were manufactured for Messrs. Mather and Platt, Limited, by the Chloride Electrical Storage Syndicate, Limited, of 16, Victoria-street, London. They have a capacity of 140 amperes for three hours, or

tourist season, entirely from the battery, which will be charged only once or twice a week as occasion may require.

The Overhead Conductors.

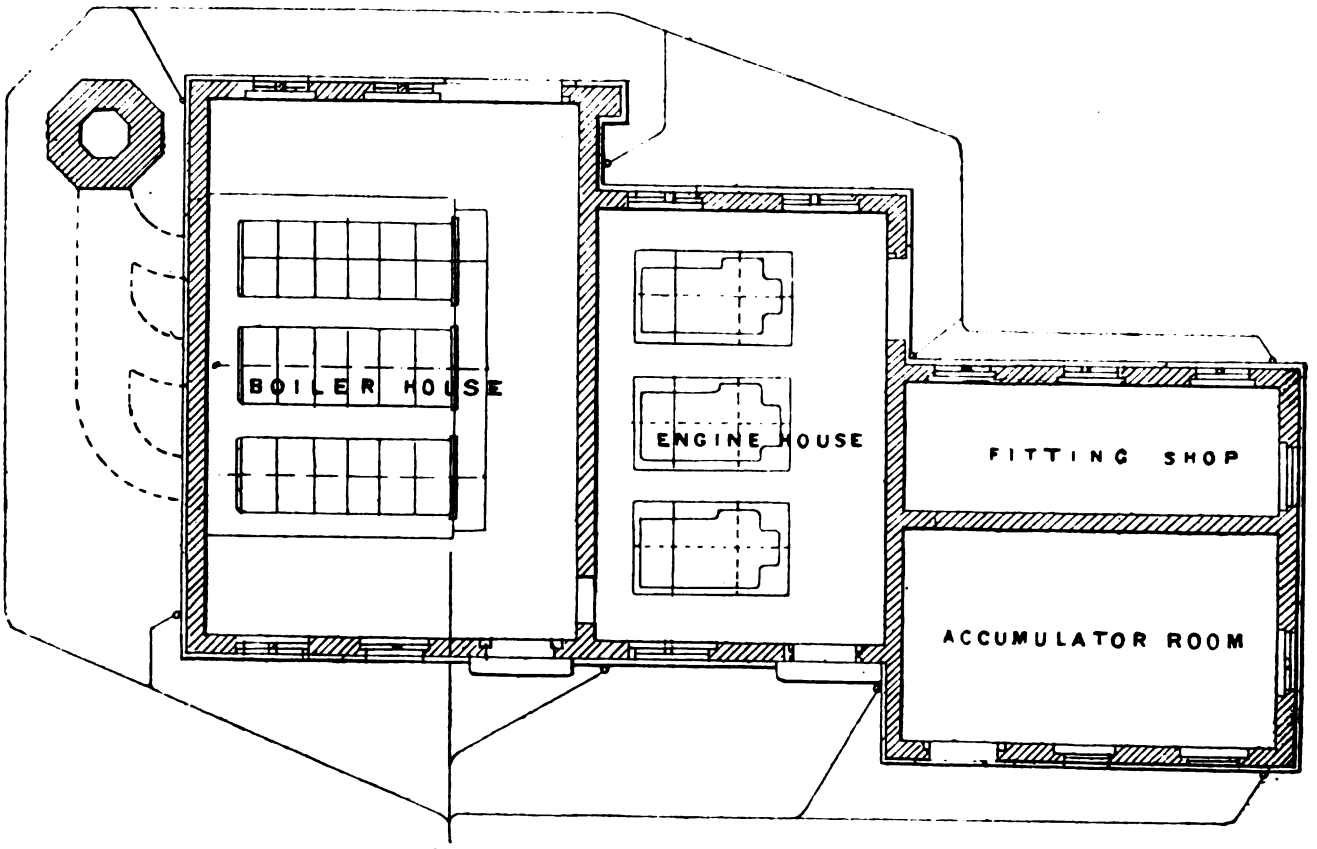
The conductors are on the overhead system patented some years ago by Dr. John Hopkinson. The current, instead of being taken from the overhead conductor by a trolley wheel, as in the case of American and other lines, is collected by two bars, each of the width of the car, and placed at each end. This arrangement will be readily seen from the illustrations. The bars rub along the under surface of the wire and make an excellent contact, much superior to the trolley system, as is shown by the entire absence of sparking. The bars clear the insulators in passing under them by about 2in., the forward bar making contact before the trailing bar breaks contact. The collecting bars are specially constructed with a hinged joint, controlled by a spring, devised by Dr. Edward Hopkinson.

Digitized by Google

This regulates the pressure of the bar against the wire, entirely gets rid of all vibration, and allows the bar to pass any unexpected obstacle without injury, such as, for instance, a broken insulator. The conductors are of high-conductivity hard-drawn copper wire, carried from insulators fixed to the cross arms of steel poles, erected with concrete bases midway between the two lines of rails.

The nine cars can maintain a service every 15 minutes in each direction, and they can therefore provide for a traffic of at least 320 passengers per hour. Since the opening of the line already 30,000 passengers have been carried in one week.

The successful completion and setting in operation of this electric tramway redound to the credit of Messrs.



Arundel Castle Electric Light Installation.—Ground Plan of Boiler and Engine House, and of Fitting Shop and Battery Room.

There is, in addition to the working conductors, a heavily-armoured feeder cable of $^{37}/_{14}$, extending about half the length of the line, and laid underground. This has been manufactured by Messrs. Callender. The conductors are broken at various points and fitted with fuse-boxes and connecting links, so that they can be connected and disconnected, as required by the regulations of the Board of Trade. The return is formed by the rails, which are bonded with copper strips riveted to the under flange of the rail, on the same system as that employed by Messrs. Mather and Platt on the Bessbrook and Newry Tramway, the City and South London Railway, and elsewhere.

THE ROLLING-STOCK.

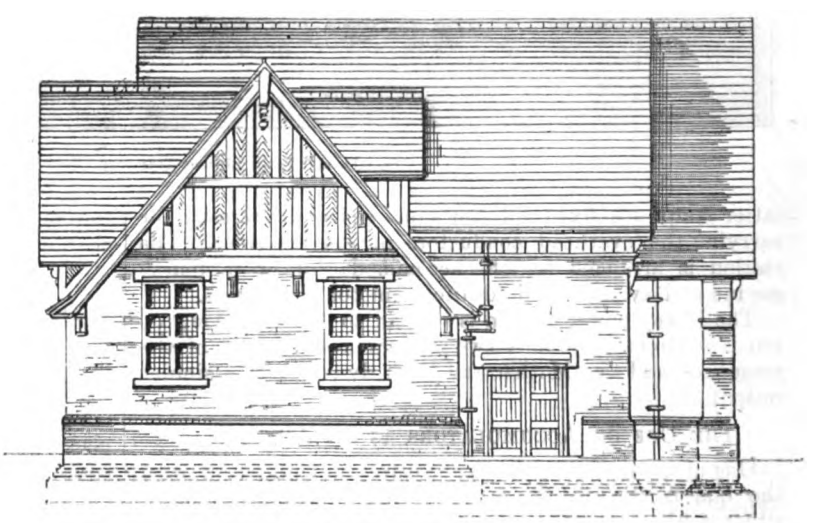
The rolling-stock comprises nine saloon motor cars, 36ft. long over the buffers, and 12 trailer cars of the "toastrack" type. The motor cars have longitudinal seats, and accommodate comfortably 38 persons. They are provided with two motors, single-reduction geared, working one on to each axle of each bogie. These motors are capable of together giving 3,000lb. tractive force at the periphery of the wheels. The motor cars, with their electrical equipment, weigh 9½ tons, whilst the trailer cars weigh four tons and will seat 44 passengers; hence a fully-loaded train of one motor car and one trailer car weighs 19 tons. The cars are equipped with powerful hand-brakes, and also with Milnes's patent continuous automatic emergency brakes, which can be worked by hand or come automatically into action if a train parts its couplings. They are also fitted with Milnes's patent coupling and buffer combined.

The cars are lighted by electricity, the current being taken from the working conductors. The absolute steadiness of the light shows the success with which the E.M.F. is maintained constant on the line.

Mather and Platt, Limited, and those associated with them in bringing the line to its present position. It is to be hoped that this tramway will be the forerunner of many others on this system in this country.

THE ELECTRIC LIGHT INSTALLATION AT ARUNDEL CASTLE.

An important electric light installation has just been completed for the Duke of Norfolk at Arundel Castle,



Arundel Castle—East Elevation of Generating Station.

Arundel. It is one of the largest private installations in the country, and is intended to light not only the castle, but also the grounds. This week we give plans and elevations of the station buildings, but hope in a future issue to

illustrate and describe the electrical plant in detail. The buildings and the general arrangements of the plant have been carried out according to the designs of Mr. A. F. Phillips, C.E., of 31, Great George-street, Westminster,

Digitized by Google

Mr. Gisbert Kapp acting as consulting electrical engineer. Mr. A. Bard, C.E., has acted as the resident engineer. The contractors for the buildings were Messrs. Reed, Blight, and Co. The whole of the machinery and electrical plant has been supplied and fixed by the Brush Electrical Engineering Company, Limited, under the superintendence of their engineer, Mr. W. Geipel, M.I.E.E., who has also laid the cables and carried out the wiring of the castle. Mr. J. E. Sayers has been in charge of the electrical section, and Mr. J. W. Donnet in charge of the mechanical department at the generating station.

The buildings containing the machinery for supplying the electric light have been erected in the new road at the top of Poorhouse-hill, near the entrance to the gardens. They have been designed in Early English or Elizabethan style, with Perpendicular reminiscences, looking as unlike an engine-house as possible. The half timbering and all external woodwork is in English oak; the roofs are of fir, and all internal timbers are of pitch pine, wrought and varnished. The roofs are boarded with wrought pitch pine. The whole of the doors are of oak strongly framed with chamfered edges. The brickwork has been carried up with dark Fareham bricks externally, and lined throughout with French grey glazed bricks internally, chamfered on the edges with a chocolate moulded skirting. The roof is covered with Ruabon tiles. The lintels and sills are of Portland stone moulded. The floors of the engine and accumulator rooms are paved with geometrical tile paving, and those of the boiler-house and fitter's shop with blue Staffordshire bricks. The chimney has been carried up in accordance with the building, its height being kept down so as to avoid its being conspicuous. The casements are all of wrought iron, with gunmetal fittings, glazed with fluted sheet glass in lead work, with special gearing for opening and closing. The building has a total frontage of 92ft., with a depth of 48ft. and 36ft. It is divided into boiler-house, engine-room, accumulator-room, and fitting-shop.

The illustrations are drawn to a scale of 16ft. to the inch.

CONTINUOUS-CURRENT DISTRIBUTION OF ELECTRICITY AT HIGH VOLTAGE.

Being a Description of the Lighting of the City of Oxford.*

BY THOMAS PARKER, M.I.E.E.

The site determined upon for the central station is situated on the banks of the Isis, some 1,500 yards from the centre of the area to be first lighted. This necessitated the use of a high-tension supply, and after due consideration the high tension continuous-current system was preferred to the alternating, as giving the decided advantage of being able to supply the light day loads with batteries when the main generating station is shut down, and also of being able to use efficient motors. At the central station high-tension continuous currents are generated at an E.M.F. of 1,050 to 1,100 volts. The current is conveyed to a central switch station, situated in Broad-street, by means of two pairs of cables, each having a sectional area of ·2 square inch, thoroughly insulated with india-rubber vulcanised and strongly braided. The insulation

* Paper read before the British Association at Oxford.

Digitized by Google

resistance is 3,000 megohms per statute mile. These cables are drawn into iron pipes. The cables are led to double-pole switches in the switch station, and by means of omnibus bars to the transformer boards. Each of these boards has an ammeter, a double-pole patent automatic cut-out combined with a switch, and a multiple contact regulating switch and resistance in the main primary circuit in series with the transformer armature. These are mounted on slate bases. Above each board is a pilot voltmeter, connected to the point in the secondary network at which the low-tension armatures supply current for distribution.

For the complete control of the whole of the transformers supplying the district, only one man is required in the switch station; if the nature of the district had allowed of the central station being placed within the city, all the switching would be done by the engineer on watch at generating station. The pilot voltmeters in the switch station show the pressure on the network, and as the load increases in any district indicates when to put on an additional motor generator. In putting a fresh motor generator on to the network, the first operation is to close the double-pole automatic cut-out which conveys the high-tension current to the transformer. The current is taken through a resistance of about 40 ohms before leaving the station and passes into the high-tension side of armature of the motor generator, and excites the field by a few turns of series wire on the magnets. The brushes on both commutators are kept permanently down, and the machine begins to revolve as a motor, the shunt, which is connected across the low-tension armature, rapidly energising the field magnets to the full saturation, so that the speed does not exceed the normal 550 revolutions. So soon as the machine is fully excited, the high-pressure primary current will have fallen to about 3½ amperes, which is the actual input with no current on the secondary. The transformer is now running "light," and the secondary E.M.F. can be adjusted by means of the multiple-contact switch and resistance coils above mentioned; when this corresponds to the pressure at that time on the network connection is made with the secondary armature and the mains. This is accomplished at the central switch station by momentarily opening and closing a small switch, which, short-circuiting the voltmeter, causes an increase of current to flow through a magnetic switch placed in the sub-station. The latter switch has its magnet coil always in circuit with the pilot voltmeter, the small current constantly passing being insufficient to affect the switch. When the voltmeter cable is short-circuited at the switch station, the resistance is so arranged that the full current required to operate the switch is allowed to pass through the wires and causes the magnet to ascend and actuate switch to complete the circuit between the low-tension armature and mains. On the switch at the switch station being again broken, the magnet drops and revolves a cam wheel to a position suitable for breaking the circuit, when the magnet is again energised from the switch station; the voltmeter now reads as before, having been only momentarily short-circuited. The E.M.F. on pilot voltmeter is kept constant by means of the regulating resistances in the primary circuit, as before explained. When the load has fallen again, which is indicated by the pilot voltmeter, the transformer is disconnected in a similar manner. First of all, the resistance is inserted until the ammeter shows that no current is being supplied from the transformer to the network, then the switch short-circuiting the voltmeter is again made and broken, causing, as before, a quarter of a revolution of the cam wheel, which this time allows a spring to pull out the contact-piece which joins the transformer to the mains. As the switch is not under ordinary circumstances broken while there is current passing, there is no sparking at the brushes, and consequently the switch requires no attention. A cut-out arrangement is provided so that in the event of too much current being supplied from the transformers to the mains, a magnet is raised, knocking the cam wheel round and breaking circuit, but leaving the switch ready to be worked again from the switch station. This cut-out also protects the transformer in event of the machine being placed on the circuit without the E.M.F. being properly adjusted, or in case a hot bearing should cause the transformer to pull up. Each transformer consists of an ordinary horseshoe magnet with a single armature, the secondary winding being placed on the top of the primary with a commutator at each end. The brushes are always left down, and as the action of the two windings neutralise each other, no alteration of lead is required for change of load. The bearings are fitted with automatic oil-pumps, which, drawing their supply of oil from a chamber contained in the dynamo pedestal, use the same oil again and again, and transformers have been working for a period of six months without changing the oil.

The low-tension distributing network consists of armoured cables. The cables consist of two sizes—*i.e.*, ½in. and ¼in. section—and are laid in a trench under the footpaths, being provided with disconnecting branch boxes, so that any section or street can be cut out. Here again, owing to the use of continuous currents, a saving is effected, there being no loss due to induction, and a pair of steel-armoured flexible cables can be used. This makes a difference in the cost and trouble of connecting up new consumers; also, as the cables themselves are flexible, a good deal of trouble and expense is saved when first they are laid where gas and water pipes are found at varying depths beneath the footpaths. The high-tension feeders to the transformers are a similar class of cable to the trunk mains, being drawn into iron pipes. At the present time there are seven transformers in use and five sub-stations. At some sub-stations two transformers are used. It was thought advisable to keep to one standard size. At the switch station at Broad-street there are installed two transformers and a battery capable of discharging at the rate of 120 amperes for eight hours. This battery will supply about one-twentieth of the load that the present station was designed for, and is capable of taking the load from about one o'clock in the morning until half an hour after sunset. The battery is charged by a small motor generator, which gives an output of 33 volts 100 amperes from the secondary armature, being supplied from the network at an E.M.F. of 103 volts on the primary. The 33 volts obtained from the secondary armature is put in series with the network, giving a total E.M.F. of 136 volts, which is sufficient to charge the cells. This may appear to be an inefficient method of charging cells, but only a small portion of the charging energy passes through the machine, and the total efficiency is 92·5 per cent. This is more economical than charging from the network with a regulating resistance, besides saving the trouble of having to arrange the cells differently for charging and discharging. The Broad-street switch station is also the offices of the company. The generating station is a brick building, some 80ft. long by 60ft. wide, built by Messrs. Kingerley, of Oxford, under the supervision of Mr. A P. Brevitt, Wolverhampton, architect. The two ends are only temporarily built in to allow for extension. In the boiler-house, which is divided from the engine-house from a party wall, are placed three steel locomotive multitubular boilers, made by Messrs. McLaren, of Leeds; these are constructed for a working pressure of 160lb. per square inch, and have proved themselves to be thoroughly satisfactory. A Green's fuel economiser is also fixed in the main flue, having 192 tubes, 4½in. diameter by 9ft. long. The engine-room is built in two spans, the engines being placed in the one next to the boiler-house, and the dynamos, which are driven by belts, are put on the opposite side, well away from dampness or dirt coming from engines, and are electrically insulated from them. At the present time three inverted triple-expansion surface condensing engines are at work; these are made by Messrs. McLaren, of Leeds, and each have cylinders 9in., 14¼in., and 22½in. diameter, with 24in. stroke. The high-pressure and intermediate cylinders are steam jacketed, and drain through a steam-trap into the hot-well. Each engine has automatic expansion gear, and runs at 125 revolutions per minute. At some exhaustive tests made in Leeds, the following figures of the boilers and engines combined were obtained:

	Jackets not in use.	Jackets in use.
Total brake horse-power	112·8	106·85
Water per brake horse-power per hour	17·671b.	15·5131b.
Coal per brake horse-power per hour	1·7671b.	1·5341b.

Digitized by Google

These figures show remarkably economical results; they have been obtained also in practice, and conduce to the low coal consumption obtained per Board of Trade unit metered.

The three Elwell-Parker dynamos, made by the Electric Construction Corporation, Limited, have an output of 1,100 volts 80 amperes at a speed of 400 revolutions, and are fitted with a third bearing outside the pulley. They are separately excited by independent small dynamos, each driven from a rope pulley keyed on to main generator shaft. The exciters are wound to give 135 volts, and are of sufficient capacity to charge a small set of cells which are used for lighting the station as well as supplying current to a small ½-h.p. motor which drives the economiser scrapers. The main dynamos are connected to a double-pole automatic cut-out and switch combined, by means of which they can be paralleled. This is a very easy matter, as no synchronising arrangement or artificial load is required. From these switches the main omnibus bar is taken to the trunk mains, each of which is controlled by a double-pole switch, so that either pair, or both together, can be used at will. The E.M.F. at the station is measured on a Kelvin electrostatic voltmeter, which is connected across the omnibus bars. The whole plant was started on July 18, 1892, and has run continuously since then, giving every satisfaction.

By the figures hereafter given it will be seen that owing to the use of continuous currents, and the contingent advantage of being able to shut down the station for such long periods, that the Oxford system is in the front rank in adaptability and economy of working. The efficiency of the transformers varies from 87 per cent. at half load to 92 per cent. at full load, and as it should not be necessary to work a transformer with less than half load the efficiency should not be less than 87 per cent. In actual practice at Oxford, as the consumers are somewhat scattered and few, it is necessary to run the transformers at less than half load during a portion of the time which has somewhat reduced the efficiency. No doubt during the next few years the gaps in the district will be filled up and then the all-round efficiency will be increased.

The figures for the year from July 1, 1893, to June 30, 1894, inclusive show that the total efficiency of the system was 62·6 per cent., the Board of Trade units generated being 195,022 and the total units metered 122,081, of which 18,303 were supplied for public lighting. There were also an additional 2,019 units used at the switch station and sub-stations. Out of the 195,022 units generated 149,668 units were obtained from the secondary of the transformers, giving an all-round efficiency for the transformers of 76·7 per cent., which includes all losses in mains and resistances. Out of the 149,668 units supplied by the transformers, 114,721 units were supplied to consumers, and 34,947 units for charging the battery. The total number of units obtained from the battery was 16,357, which makes the battery efficiency of the year 43·9 per cent. Adding the 16,357 units obtained from the battery to the 114,721 units obtained from the transformers, we get a total output of 131,077 units supplied to circuits. The total metered was 124,101, including those used at switch station, so that there remains 6,976 units unaccounted for, or not quite 5½ per cent. As the current is supplied at 102 volts, and metered at 100, 2 per cent. is thus accounted for, and the rest is probably due to error in instruments or observation of reading, these having been taken half-hourly throughout the year, the tendency being naturally to over-read than to under-read the instruments. In all the following figures of cost, the units metered have been taken as the basis, leaving out as losses the difference of supplying at 102 volts and metering at 100, and also the current used at the works. The actual coal used during the 12 months was 6·43lb. per unit sold. During this period the cost of coal, which was best Welsh, averaged 21s. 10d. per ton, working out to ·752d. per Board of Trade unit. The cost of coal increased during the coal strike and still remains high. In comparing this cost with that of other stations, due consideration must be given to the total output, being only just over 100,000 units, whereas Newcastle and Bradford, which I believe are the only stations which spend less per unit on their coal, have a total output in 1893 of 360,000 and 480,000 units respectively.

The total number of 8-c.p. 35-watt lamps installed on June 30, 1894, was 7,774, whereas on July 1, 1893, there was only 5,060 connected to the mains. As in Oxford the colleges form a large portion of the supply, the term time is the only part of the year when a load can be obtained, so that last year only for about eight weeks was even half the plant required at the maximum load, and the system has to be very elastic to cover it and show good results. The total cost of all generating expenses, including all rates, taxes, and rent, was 3·715d. per unit delivered to consumers. The cost is divided up as follows:

Coal	·752
Oil, waste, water, and engine-room stores	·042
Wages, including engineer	1·221
Repairs and maintenance of public lamps	·366
Repairs and maintenance	·907
Rents, rates, and taxes	·427
	3·715

Management and office expenses cost 1·534d. per unit, making a total of 5·249d.

In the above figures, due regard must be paid to the fact that for the greater part of the year only about half load for one engine was ever required, so that more than double the output could have been supplied with slight increase in wages, and little extra on maintenance. Thus, with double the output, the figures would have been somewhat as follows:

Coal	·752
Oil, etc.	·042
Wages	·650
Repairs	·450
Public lamps	·183
Rents, etc.	·214
	2·291

which figures are good with so low an output as 240,000 units.

The revenue for the year from lighting was £3,715. 8s. 2d., giving 10s. 11d. per 35-watt lamp installed, the number of units used being 18·2 per lamp throughout the whole year, and the average price obtained 7·3 pence per unit.

The load-factor at Oxford only works out to 5·93 per cent. By the expression "load-factor," is meant the ratio of the units sold to the units that could be sold with all the lamps always on—viz.:

$$\frac{\text{Metered watt-hours} \times 100}{\text{Mean watts installed} \times \text{number of hours in the year.}}$$

I have to thank Mr. J. H. Woodward, A.M.I.C.E., and Mr. E. S. G. Rees for their assistance in the designing of the system; also to Mr. J. H. McLean, who has put down the plant, under my direction, for the Electric Construction Corporation. He is now engineer to the Oxford Company, and has given us his assistance here to-day.

SOME ADVANTAGES OF ALTERNATE CURRENTS.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

Amongst electrical engineers there remain a few, chiefly of the old pioneers, who have not grasped the advantages possessed by alternate currents over continuous currents in systems of electric supply. Superstitions still linger that alternate currents are less easy to manage, or are less economical, or are more dangerous, or are less readily measured than continuous currents. There is a special superstition that they cannot drive motors. Such superstitions once set afloat die hard, and, sad to relate, they are sedulously fostered by a few interested persons who ought to know better. The present paper is intended to point out a few of the more salient advantages attendant on their use, and to add a few points that have recently claimed the writer's consideration and are not generally known.

It is well known that the economic transmission to a distance of electric energy depends for its success on the use of high voltages or pressures. The reason is that power depends on the product of two factors—current and pressure, and that of these two factors

* Paper read before the British Association at Oxford.

Digitized by Google

the former, current, involves some waste in the conductors. If large currents are transmitted at low pressures, there will be either much power wasted as useless heat in the copper conductors, or else the conductors must have such large cross-section that the interest on their prime cost involves a still more serious waste. If small currents are used at high pressures—1,000 volts, 5,000 volts, 10,000 volts, as the case may be—the copper conductors may be small and the interest on their cost a trifling quantity. Now, this all-important fact to the electrical engineer is absolutely independent of the nature of the current as to whether it is continuous or alternating. The advantage of alternating over continuous currents come in in the circumstance that high pressures cannot be used in houses without being transformed down to low pressure. Hence the system which admits of transformation by a stationary transformer, consisting merely of two coils wound upon a common core, is to be preferred over that requiring running machinery for transformers.

Again, it is an advantage not only for high-voltage systems, as distinguished from low, but in all systems, whether high or low, in which currents of considerable magnitude have to be collected and delivered, that there should be no necessity for employing either in the generating plant or in motors any commutators or sliding contacts, with their adjustable brushes and the like paraphernalia. The commutator, the indispensable adjunct of the continuous-current dynamo and motor, has long been known to be its weakest part from the engineering point of view. It is complex and costly as compared with other parts. It requires far more attention than any other part of the machine. It undergoes greater wear; and the circumstance that under conditions not far removed from normal it may give rise to serious sparking, is also a disadvantage.

Alternate-current generators have no commutators. Those types of alternators in which the armature revolves require, indeed, collecting rings (for sliding contacts) and brushes, a device to which the foregoing remarks on commutators scarcely apply, seeing they need no adjustments nor give rise to sparks. But the type of alternator now coming most in favour do not even require these (except on the exciting circuits, where their disadvantages are nil), since in them the high-voltage armature parts are stationary. The only parts that need revolve are most substantial masses of iron and copper needing no special insulation in their construction, or attention in their operation. To be spared all the troubles arising from commutators and brushes is no small advantage in itself to the central-station engineer.

Another advantage of an entirely different character is the greater safety of the alternate currents. With them there is far less likelihood of trouble from leaks in the distributing circuit than if continuous currents were used at the same voltage. This arises from the circumstance that the electrolytic action of the alternate current is so extremely small. If there is a weak point in the insulation of a main or branch conductor where damp can get in to form a path for leakage, the continuous current will find it out and promptly set up chemical corrosion. Corrosion sooner or later ends in setting up an arc, and an outbreak of fire results. The corrosion of water and gas pipes complained of in many districts where a continuous-current supply is maintained are unknown where alternate currents are used. The danger to life for equal voltages is, I think, now established to be greater with continuous currents than with alternating, as their destructive action on the tissues is greater.

Again, it is no light matter that while in a continuous-current supply there is but one way of moderating or regulating the strength of the current which flows to a lamp or motor from the supply mains at a given pressure, there are two modes of regulation possible if the supply be one with alternating current. In the continuous-current case we regulate by introducing resistances, which regulate by wasting power. It is as though when we wanted to put a slow speed on to a power lathe we did it, not by changing the gearing, but by putting a grindstone on the same piece of shafting and slowed it down by grinding something that would waste the power. But in the case of alternate currents—though we may still, if we please, regulate by wasteful means—we have another and non-wasteful way available in regulation—viz., the use of so-called choking coils, or reaction coils, which operate by setting up opposing E.M.F.'s in a purely automatic way—damming back the currents instead of wasting them. The use of choking coils is destined to find a very great increase in services of this kind.

It would be travelling too far from the range of this paper to enter to any great length upon the work that has been done during the past five or six years with combinations of two, three, or more alternate currents in different phases. Two-phase and three-phase combinations of alternate currents, using three or four wires for their transmission instead of the ordinary two-wire system of conductors, are now quite well known, and their advantages in special cases are fully recognised. Of course, it will be at once replied that any phase system of currents—that is, a combination of two or three alternate currents, and require three or four wires instead of two—cannot be entirely an advantageous system as compared with simple continuous currents, being more complicated. This is very obvious, and yet the fact remains that with two-phase and three-phase systems of current one can accomplish results which the simpler systems cannot accomplish, and meet conditions which the simpler systems cannot meet. Without attempting any complete exposition of the phasal systems, let one or two points suffice for remark. It has been found essential, or, at least, advantageous, in those districts where continuous currents are used on a large scale, to depart from the sweet simplicity of the two-wire system, and in order to economise in the total cost of copper in the mains to adopt a three-wire, or a four-wire, or even a five-wire distribution, so that sweet simplicity is not always on the side of continuous currents. Again, if a three-wire three-phase system of alternate currents is used, the total weight of copper needed in the conductors (at equal voltage) is less than in the ordinary two-wire system for an equal amount of power, whether that two-wire system be with continuous currents or with alternate currents. The main advantage of three-wire polyphase alternate-current systems (whether three-phase or two-phase) is, however, the greater facility that they offer in the handling of motors, since they are more readily made self-starting than is the case where merely single alternate currents are supplied on a two-wire system of distribution.

At the Electrical Congress of Chicago, in the debate on a paper by Mr. Scott, of the Westinghouse Company, on polyphase systems, the writer expressed the opinion that while a polyphase system was adopted to the case of the transmission of power from a single generator to a single motor in the generality of cases in which the power was to be not only transmitted, but distributed to a number of motors at independent points, the great simplicity of the simple alternating current, greater simplicity of the simple alternating current, would render it preferable now that self-starting motors were in the market. Bearing, however, in mind the advantages to be derived in the possibility of using two and three phase motors, the author gave considerable thought during the winter to the problems of transformation, and particularly to the question whether it might not be possible to transform alternating currents from two-phase to three-phase, or from either of these to single-phase, or *vice versâ*. No mode of doing this was known save by the combination of motor-generators as running machines. As one result of his cogitations, he found that such transformation might very readily be effected by stationary transformers, or in the least easy case by stationary transformers with a revolving iron core. The simplest case—that of transforming three-phase currents into two-phase (or *vice versâ*)—involved no moving parts, being effected by using a ring coil (or its magnetic equivalent) with connection made appropriately. For example: if a Gramme ring is connected, as shown in Fig. 1, to a two-phase system with 100 volts

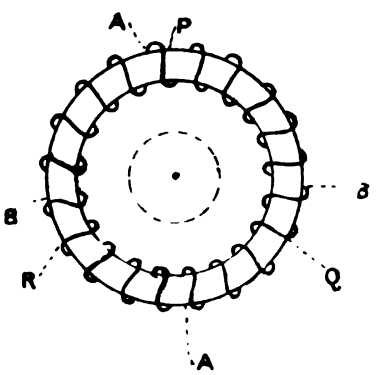

FIG. 1.

between A A, and 100 volts in quadrature between B B, a three-phase set of alternate currents may be taken off from the same winding at three equidistant points, P, Q, R, at pressure of 66 volts between each of the three wires. The magnetic field across the coil revolves, and it is preferable to provide a laminated core to complete the magnetic circuit. Such a core may be stationary, or may revolve. A simple ring transformer like the above (without revolving coil) was shown by the author at his lecture on the transformations of electric currents, at the Royal Institution on February 23, 1894. It is of some interest to note that on March 7 Mr. Scott read an elaborate paper to the American Institution of Electrical Engineers, in which he gave an independent solution to the very same problem, using two sets of winding (instead of one), but working out in detail many possible applications. It is no exaggeration to say that an electrical engineer starting, let us say, with three-phase alternate currents as the method of supply, is in a position to furnish any customer who may desire either two-phase currents or single-phase currents with what he desires by merely putting in a small appropriately connected transformer. Another advantage, about which even electrical engineers are as yet almost wholly unenlightened, arises in the application of alternate currents to electromagnets. Great as

Digitized by Google

have been the services of electromagnets as used with continuous currents since their invention in 1825, they are destined to fulfil wider services than ever in the practical problems of an electro-mechanical nature now that their properties, when supplied with alternate currents, are becoming known. In 1887, Prof. Elihu Thomson discovered a number of singular properties of alternate-current magnets in producing repulsion of copper discs and rotation of cylinders and balls by reason of the eddy currents induced in them. During the past winter the author has been studying the design, construction, and properties of alternate-current magnets, and recently, in conjunction with his assistant, Mr. Miles Walker, read a paper on the subject before the Physical Society of London. A few words on this topic will emphasise the advantages offered by alternate currents in this application. It has long been known that the magnetic forces of a magnet fall off very rapidly at small distances from their poles. For steel magnets in those cases in which the poles can be considered as points, the force falls off inversely as the square of the distance, other things being equal. In the case of soft iron electromagnets operated by continuous currents, the pull on their armatures falls off much more rapidly than this. The forces when in contact may be relatively enormous, and yet the magnet may have no range of attraction worthy of mention. A pull of 150lb. in contact may dwindle to a few ounces at a distance of a couple of inches. But with alternate currents supplied at constant voltage from the mains, the author finds all this to be different. With a properly-designed and well-constructed electromagnet, the pull on its armature can be kept fairly constant over a considerable range—nay, in some cases can be caused to be greater at a distance than when near. For example, the author has lately had an alternate-current magnet constructed for him by Mr. Walker, the pull of which, when excited at 50 volts, was 8oz., when the armature was closely in contact with the core, but which exercised a pull of 32oz. when the space between them was 3in. This obviously introduces into electric mechanism a new element hitherto undreamed of.

The secret of these things is that in the case of alternate-current electromagnets, the self-induction reaction of the system, and not the mere electric resistance of the wires, is that which governs the flow of current, whereas Ohm's well-known law for continuous current is

$$\text{Current} = \frac{\text{Electromotive force}}{\text{Resistance}}, \text{ or } C = \frac{E}{R}.$$

The rule that governs the alternate current in these cases is different, being

$$\text{Current} = \frac{\text{Electromotive force}}{\text{Reactance}}, \text{ or } C = \frac{E}{pL},$$

where p is the pulsation of the alternate current—*i.e.*, the number of radians per second in the revolutions of the circle of reference—and L the inductance.

As the armature of the alternate-current magnet is withdrawn from the core, the reactance diminishes and more current flows, making the pull greater at a distance instead of less.

Another curious point about alternate-current magnets relates to their winding. In the case of electromagnets supplied with continuous currents, it is well known that the more turns of wire that are wound on the core the more powerfully is it magnetised. But with alternate-current magnets this is not so. There is one particular number of windings for each magnet (generally a small number) for which the magnetism is a maximum, and any additional wire wound on above this number diminishes instead of increasing magnetic power.

Returning from this digression respecting magnets to the general question of the supply of alternate currents, the author has finally to point out one further set of advantages hitherto both neglected and unknown in this country, though known to a few and actually in use in the United States.

One of the difficulties which beset the distribution of electric currents on the large scale is that of maintaining constant, at all points of the network of conductors, the voltage or pressure at which the current is delivered to the consumers. Between the generating station and the centre of distribution there occurs a loss of pressure (comparable to the loss of head in the case of water power), and beyond the centre of distribution, between it and the points of consumption in the house lamps, there is a further drop in the voltage. The former drop in the voltage can be compensated for by due arrangements at the central station, but the further drop between the distribution centre and the consumers' houses, though it may be guessed at and partially compensated by some system of over-compensating at the distribution centre, cannot be accurately compensated. The result is that the consumers' lamps do not receive their supplies of current at an unvarying pressure. Now in the case of continuous-current distribution the only cause for drop in the voltage at distant points is the resistance offered by the conducting wires leading o those points. The drop due to such resistance—or ohmic drop—is proportional to the ohms of resistance and to the amperes of current. Suppose a group of lamps requiring 20 amperes at some outlying point, the wires to which have a total resistance of only one-tenth of one ohm. The drop in voltage due to the ohmic resistance will be $20 \times 1\text{-}10 = 2$ volts. The lamps, which ought to receive their currents at a pressure of 100 volts only, return it at 98, and burn dimly in consequence. But in the case of alternating currents there is a second or additional cause of drop, which has hitherto been held to be a serious disadvantage in their use—namely, a drop due to the self-inductive action of the lines reacting and setting up back E.M.F.'s and tending to choke the current. In general, this second or inductive drop is not serious, the mains and branches being arranged concentrically for the purpose of avoiding it as far as possible; but it may become serious when motors as well as lamps are employed upon the circuit, because of the considerable inductive reactions that are set up in the electromagnetic operations of these machines.

Alternate-current motors are of many sorts, but may be grouped under two chief classes—the synchronous and the asynchronous. Synchronous motors are those which only run at one fixed speed, determined for them irrespective of their load—a speed determined solely by the number of their own poles and the number of the alternations imposed upon the current by the generating machinery at the station. They must either run in synchronism with the pulsations of the current or else not run at all. The other class, the asynchronous, are mostly polyphase machines requiring two-phase or three-phase currents to operate them. The phase currents led into a suitable armature, there combine to produce a rotating magnetic field, and in this rotating field masses of iron or iron carrying closed circuits of copper are set into rotation, being magnetised inductively, and dragged round by the reaction of the eddy currents induced in them. The rotor, or rotating part, of the asynchronous motor may be regarded as a revolving field magnet not magnetised by any special exciter or initially, but magnetised only by the eddy currents induced in it. Now, if it could spin at the same rate as the revolving magnetic field that surrounds it, there would be no relative motion, no eddy currents, no reactions, and no driving force. It is driven by forces which depend for their existence upon the rotations not being synchronous with the pulsations of the currents in the circuits. Within certain limits it adjusts its speed so that its magnetic slip is proportional to the turning moment which it is called upon to exert.

Now, owing to these necessary reactions, the asynchronous motors produce upon the mains which supply them an inductive drop, and cause the pulsations of current to lag in phase behind the impressed pulsations of voltage. Whereas the ohmic drop is not accompanied by any lag of phase in the current, the inductive drop is so accompanied. Happily, with alternate currents, there exists more than one remedy. It has long been known that a condenser exercises a reaction of another kind, which, though it tends to choke the current, does so not by retarding the phase of the pulsation, but by accelerating it. This precious property has long been known and used in submarine telegraphy to compensate, by the use of condensers, the retardations of the signals. But to apply condensers to systems of alternate-current supply for the purpose of counteracting the inductive drop when motors are used, would be a rather formidable task; the remedy is too heroic for the malady. A remedy of a different kind is, however, possible, and must before long become general when its advantages are known. To explain it we must return to the subject of synchronous motors, about which little has been said. It was shown in 1868 by Wilde, and in 1879 by Hopkinson, that two alternate-current machines could run together synchronously, one as generator, the other as motor, the one which served as motor adjusting itself so that its pulsation of E.M.F. tended (as in all motors) to oppose those of the impressed E.M.F. In 1884, Dr. Hopkinson further predicted that an alternate-current machine could run as a motor even if its mean E.M.F. was higher than that of the circuit, a result verified in practice by Mr. Mordey in 1890. In 1892, Mr. Mordey gave at the Institution of Electrical Engineers some further results of alternate-current working, including a very remarkable curve, here reproduced, showing the dependence of the armature current upon the excitation of the field magnets of the motor when loaded with a given load. To this curve and its meaning the author directed attention at the time, and he has since given much thought to it. It will be found to be most significant. The curve presents the form of a letter V. The lowest point corresponds to a particular state of things—namely, that the motor having its magnetism excited to a practical degree, draws a certain minimum amount of current from the mains in order to drive its mechanical load at the speed imposed upon it. But to do the same work, drive the same load at the same speed, will take more current from the mains if the excitation of the magnets is either more or less than this particular amount. This seems very strange, but the explanation and its consequences are no less so. The particular stage of excitation which makes the armature

Digitized by Google

current a minimum for the particular load in question, is that stage which corresponds to there being no difference of phase between the pulsations of impressed voltage and those of the resulting current. Suppose, for example, the armature had a resistance of ½ ohm, and that the current was supplied at 100 volts, and that a current of 10 amperes was found the minimum current that would drive the load. It would be found (approximately) that the excitation corresponding to this minimum current would be such as would make the motor work with a back E.M.F. of 95 volts, for then by Ohm's law $(100-95) \div \frac{1}{2} = 10$ amperes. But now suppose the excitation is lessened, the machine, acting at the same unalterable speed, will generate less than 95 volts. Suppose it drops to 90 volts.

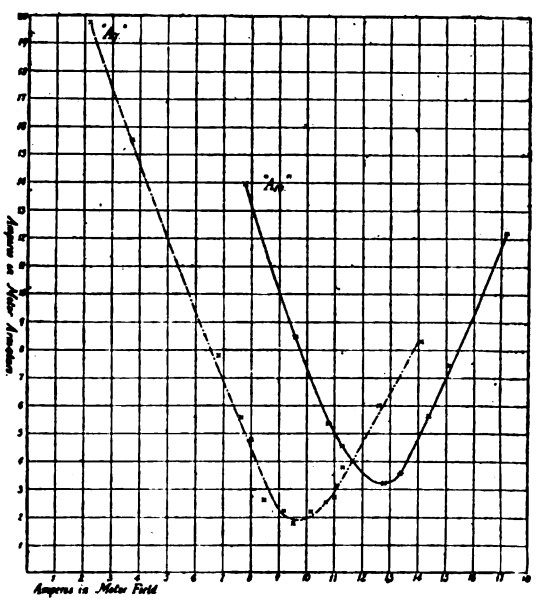

FIG. 2.

Then, if nothing else happened, the current would increase to $(100 - 90) \div \frac{1}{2} = 40$ amperes. But 40 amperes at 90 volts is much more power than 20 amperes at 95 volts, and is more than is wanted for the load. What must happen? The machine is synchronous and cannot—physically cannot—run faster so as to take up this power. It tries to do so, with the result that it shifts the phase of its readings, the current now lagging in phase behind the impressed E.M.F.—choked down, in fact, from the 40 amperes to something more than 20. Choked down, in fact, in such an amount as would, if multiplied by the cosine of the angle of lag and by the 90 volts, come up to the same product as the original volts and amperes—viz., $95 \times 10 = 950$. The synchronous motor, if *under*-excited, acts, then, as a choking coil, producing a reaction drop. But continue the experiment the other way. Suppose the excitation is increased so that the 95 volts becomes 100 volts $(100 - 100) \div \frac{1}{2} = 0$, and there would be no current at all to drive did not an adjustment of phases come into play. Instead of the current dropping to zero, more current than before now comes into play, and that current has its pulsations in advance of those of the impressed voltage, there being now an angle of *lead* in the phase relations. In other words, the synchronous alternating motor, if *over*-excited, acts as a condenser, and instead of producing a drop in the voltage tends to raise it by compensating the inductive drop due to self-induction in other parts of the circuit. When the importance of this deduction from Mr. Mordey's curve dawned upon the author, he began to prepare to test it upon the mains of the City of London Electric Light Company. But before any experiments could be even arranged he learned that the same conclusions had been arrived at by the officials of the General Electric Company at Lynn, Massachusetts, and that they had found it in practice to work out favourably. By the courtesy of Mr. W. F. Parshall, one of the engineers of that company, who has been associated for long with Prof. Elihu Thomson, Mr. Steinmetz, and other engineers, the author is able to state the following particulars. They found that in a line where self-induction played the part of a choking coil, it did not matter very much whether the voltage needed for driving the current through the line and machine were situated mainly in the generator or in the motor, as the mean voltage in the line was not far from a mean between that of the two. Accordingly, in a three-phase power transmission at Hartford, Conn., of 300-kilowatt output the motor was arranged to be over-excited. Later, after Mr. Steinmetz had submitted the question to calculation, this feature was introduced into the synchronous motors used in all their recent power transmissions, so that by proportioning the armature reaction and the over-excitation to the self-induction likely to arise, the voltages on the circuit remain quite constant regardless of load within the capacity of the machines. In thanking Mr. Parshall for his information, I may add two points of comment. The advantage so to be derived from over-excitation have indirectly another advantage—viz., that for single transmission cases the motor and the generator may be designed and constructed as identical machines, instead of the motor being made smaller than the generator. Further, the regulation of the voltages in such a network as that of the City of London Electric Light Company, instead of being made more difficult when motors are much used—as was feared by some engineers—will be more easy, provided the motors are of the over-excited synchronous type. For the acceleration of phase these produce in the current, not only tends to compensate for the inductive drop in mains and transformers, but tends to reach right back through the system to the generators in the central station, acting on them as a compound winding would, and assisting them, not only to counteract the inductive drop, but also the ohmic drop, both between the consumers' lamps and the distributing points, and also between these points and the generating station.

So manifest is this advantage, that it would seem worth while to erect at one or possibly more points of the network, as remote as possible from the generating station, synchronous motors over-excited to act as condensers in compensating the inductive drop, or in the primary circuit, also to furnish the idle currents for magnetising the transformer primaries.

With such possibilities open in the future for alternate-current working, and with such advantages in respect of motive power over continuous-current working, it can hardly be doubted that, save in a few special cases, the vast majority of central stations will henceforth be operated by alternate currents.

EXCURSION OF THE ELECTRICAL COMPANY'S EMPLOYES.

The employés of this company, together with their wives, met recently at 122, Charing Cross-road, at 10.30 a.m., where light refreshment was served. Mr. C. R. Fownes, of Montague-street, Montague square, W., supplied two four-in-hand coaches, which started at 11 a.m. Mr. F. T. Eggers, the general manager of the company, tooled one coach, and Mr. Fownes the other. After an enjoyable drive the party arrived at the Thames Hotel at 1.15, where dinner was served. Several toasts were then given, and a speech was made by the general manager, Mr. F. T. Eggers.

Mr. Eggers, in the course of his remarks, stated in reference to the passage-at-arms which took place lately in the House of Lords between a former and a present Prime Minister concerning the aliens, that he would welcome those foreigners into England who conducted themselves in a proper manner, and give those who did not a free pass back to their native land. Concerning electricity, he remarked that when properly manipulated it provided the necessaries for our natural life. If occasionally they met with a loss, it was no doubt only to remind them that their racer, although first favourite, required extremely careful handling. They must not forget their directors, as they had to thank them for the handsome way in which they voted the funds for the outing, besides contributing personally in a very liberal manner. The speaker took the opportunity of thanking all the employés of the company for the considerate way in which they had rendered his task of conducting the firm's business a pleasant and an agreeable one. Friction could of course not altogether be avoided, but in an engineering firm, more so than any other, they ought not to forget that they were all in the same boat, and that they were expected to pull together. Two years ago they were still in the midst of difficulties, which every young concern had to overcome. To-day, with English foresight and German perseverance, they had obtained a place among the most responsible and successful concerns of the electrical world in the United Kingdom.

The toast of "Success to the Electrical Company, Limited," having been honoured, Mr. Eggers was complimented on the successful manner in which he had conducted the firm's business, and his health was drunk with musical honours. The engineer, **Mr. Buhler**, who had just returned from the Continent, proposed the toast of "The Company's Headquarters—The General Electricity Company of Berlin." After dinner some of the party went for a trip up the river in a steam-launch, on the way picking up others who had previously gone to the Vernon Club. Tea was served at six o'clock, and at seven o'clock the coaches started home, reaching Charing Cross-road about 9.30. The weather was everything that could be desired, and a very enjoyable day was spent.

Thomson-Houston System.—The Laing, Wharton, and Down Construction Syndicate, Limited, have acquired for the United Kingdom the patent rights of the Thomson-Houston system for electric lighting and transmission of power, and they will in future carry on business under the new title of the British Thomson-Houston, Limited.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

NATIONAL TELEPHONES.

The long-expected blow has at last fallen—and no one is seriously hurt. For many months, reaching even into years, there have been protracted negotiations going on between the Post Office and the telephone interests: and naturally enough the longer the delay in reaching some definite conclusion or final working arrangement, the greater was the pitch of expectation to which we were all worked up. Rumour indeed was rife to the effect that, after suffering a pretty heavy set-back when the New Telephone Company secured advantageous arrangements with the Post Office two years ago under the auspices of the late Duke of Marlborough, the National Telephone Company had obtained on that nobleman's death such a strong position that the Postmaster-General was practically under their thumb, and nothing less than absolute autocracy in every detail was to be expected in the telephone service for the remainder of the company's existence.

Probably these reports were prompted by a fear of the worst—at any rate, they were hardly founded on fact. The real reason for the delay has more likely been because the National had nothing to gain by hurry, but rather might hope to secure their position in every minute detail by careful discussion of the final agreements which required drafting and accepting in view of the provisional trunk line arrangements already made.

It was, however, hardly to be expected that any serious opposition could be presented by the National Company towards proposals emanating from a Government office. Of course it is quite possible (as was shown by the Board of Trade draft regulations for electric tramways) for Government officials in their zeal for the general welfare to draft rules which might conceivably give temporary advantages on one side or the other; but the reputation of any department for impartiality would prevent such rules from being finally adopted if their effect is pointed out. The shareholders in the National Company might therefore have every confidence that their interests would not be overridden.

Can the same be said of those who, after all, are the mainstay of any telephone service, whether National, New, or Post Office? We mean the subscribers, who too often have just cause for complaint as regards the manner in which their money is taken without an adequate service being rendered. On the whole, it would appear that they will not at any rate be worse off than has been so far the case; and to those who read between the lines, the present parliamentary return just issued (containing what is practically a *précis* of the draft agreements and heads of arrangement already signed) may fairly be said to mark another prominent step towards the final surrender of all telephone business to the State when the National Company's license expires in 1910—that happy day when the question of metallic circuits will not be left for solution to directors or dividends, but will be regarded more as an essential of sound telephone engineering.

At present, however, the agreements now drawn up are concerned mainly, if not entirely, with the

Digitized by Google

trunk lines, which, according to the arrangements made two years ago, are to be taken over by the Postmaster-General, and the matter of supreme importance is that of the terms upon which such transference is to be made. These, speaking generally, are in substance identical with the working arrangements outlined in 1894. For instance, the trunk lines already constructed by the National Company are to be taken over at a price equal to the estimated cost thereof to the company (including in such cost all reasonable incidental expenditure), together with a further sum of 10 per cent. of the amount of cost (an item added in respect of cost of administration), and this estimated cost is to be ascertained by two experts in telegraphic engineering, one to be appointed by the Postmaster-General, and the other to be appointed by the company. All differences between such experts are to be settled by arbitration in a summary manner upon the respective statements of such experts, or upon such other materials as the arbitrator may require, but *without the aid of counsel*. It was at first proposed that the purchase-money for these lines should be the cost price thereof as shown by the company's books, plus 10 per cent.; but, "strange to say," the company's books do not show in detail such cost price. The initiated would not wonder at this, but we let the fact pass for the time being.

This arrangement appears to be of a thoroughly business like nature, and those who have no fondness for the law and its intricacies—its quips and cranks, not to say quodlibets and quillets—will feel no great displeasure at the italicised words of the above paragraph. To argue out any matters thus in dispute—especially of so technical a nature—does not require lawyers but engineers, and this procedure might be adopted with advantage elsewhere.

There are, however, two points which require comment in this draft arrangement as to payment for the trunk lines, which, after all, is the most important feature to be discussed. Much will depend upon the experts who are thus to be appointed. We shall in the meantime assume that men of the first calibre will be chosen, men whose decision will be arrived at conjointly and remain unquestioned; but there need be no scruple in calling an undesirable appointment into question.

The next point is that no specific mention is made as to the election or choosing of an arbitrator, unless it be understood that the experts themselves are to decide and call him in to settle matters disputed between themselves. Doubtless this point will be amicably settled in any of the well-known methods: but we would fear difficulties in these directions rather than others.

The National Company is now provided with a definite list of exchange areas within which—and nowhere else—its business may be developed; the Post Office takes over the trunk lines upon terms which may and ought to prove satisfactory, and so we enter upon the second and last stage of the telephone monopoly's existence. When that is ended we shall probably send our complaints (much fewer, let it be hoped) to St. Martin's-le-Grand instead of to Oxford-court. In any case, we can only exchange King Stork for King Log.

THE BRITISH ASSOCIATION.

In another part of this issue we publish some of the papers read before the association, and below we give abstracts of other papers which were also read at the meetings.

Preliminary Experiments for Comparing the Discharge of a Leyden Jar through Different Branches of a Divided Channel.

BY LORD KELVIN, P.R.S., AND ALEX. GALT, B.SC., F.R.S.E.

In these experiments the metallic part of the discharge channel was divided between two lines of conducting metal, each consisting in part of a test-wire, the other parts of the two lines being wires of different shape, material, and neighbourhood, of which the qualities in respect to facility of discharge through them are to be compared.

The two test-wires were as nearly as we have been hitherto able to get them equal and similar, and similarly mounted. Each test-wire was 51cm. of platinum wire of ·006cm. diameter and 12 ohms resistance, stretched straight between two metal terminals at the ends of a glass tube. One end of the platinum wire was soldered to a stiff, solid brass mounting; the other was fixed to a fine spring carrying a light arm for multiplying the motion. The testing effect was the heat developed in the test-wire by the discharge, as shown by its elongation, the amount of which was judged from a curve traced, by the end of the multiplying arm, on sooted paper carried by a moving cylinder. Two of Lord Kelvin's vertical electrostatic voltmeters, suitable respectively for voltages of about 10,000 and 1,500, were kept constantly with their cases connected with the outer coatings of the Leyden, and their insulated plates with the inside coatings of the Leyden.

1. In the experiments hitherto made the two wires to be tested have generally been of the same length. When they were of the same material, but of different diameters, the testing elongation showed, as was to be expected, that the test-wire in the branch containing the thicker wire was more heated than the test-wire in the other branch. In a continuation of the experiments we hope to compare hollow and tubular wires of the same external diameter, and same length and same material.

2. With wires of different non-magnetic material—for example, copper and platinoid—of the same length, but of very different diameters, so as to have the same resistances, the testing elongations were very nearly equal.

3. In one series of experiments the tested conductors were two bare copper wires, each ·16cm. diameter, nine metres long, and resistance ·985 ohm, which, it will be observed, is very small in comparison with the 12 ohms in each of the platinum test wires. One of the copper wires was coiled in a uniform helix of 40 turns on a glass tube of 7cm. diameter. The length of the helix was 35cm., and the distance from centre to centre of neighbouring turns therefore $\frac{7}{8}$cm. The middle of the other copper wire was hung by silk thread from the ceiling, and the two halves passed down through the air to the points of junction in the circuit. The elongation of the test-wire in this channel was more than twice as much as that of the test-wire in the channel, of which the helix was part.

4. One hundred and seventy-one varnished pieces of straight soft iron wire were placed within the glass tube, which was as many as it could take. This made the testing elongation 10 times as great in the other channel.

5. The last comparison which we have made has been between iron wire and platinoid wire conductors. The length of each was 502·5cm. The diameter of the iron wire was ·034cm., and its resistance 6·83 ohms. The diameter of the platinoid wire was ·058cm., and its resistance 6·82 ohms. Each of these wires was supported by a silk thread from the ceiling attached to its middle (as in 3 and 4 for one of the tested conductors). Fourteen experiments were made, seven with the test-wires interchanged relatively to the branches in which they were placed for the first seven. The following table shows the means of the results thus obtained, with details regarding the electrostatic capacities of the Leyden jars and the voltages concerned in the results.

In each case four Leyden jars, connected to make virtually one of capacity ·02742 microfarad, were charged up to 9,000 volts, and discharged through divided channel. The energy, therefore, in the Leyden before discharge was $11{\cdot}105 \times 10^6$ ergs. In each of the first three cases 1,450 volts were found remaining in the jars after discharge; in each of the last four 1,400.

The mode of measuring the elongation of the test-wires was, as may be understood from the preceding description, somewhat crude, but it is reassuring to see that the mean results in the cases of 10·82 and 10·84 megalergs of energy used are so nearly equal. The ratios for the two circuits are, in the two cases, respectively 1·48 and 1·46. The conclusion that the heating effect in the test-wire in series with the platinoid wire is nearly one-and-a-half times as great as that of the test-wire in series with the iron is certainly interesting, not only in itself, but in relation to Prof. Oliver Lodge's exceedingly interesting and instructive experiments on alternative paths for the discharge of Leyden jars, described in his book on "Lightning Conductors and Lightning Guards," which were not decisive in showing any general superiority of copper over iron of the same steady ohmic resistance, but even showed in some cases a seeming superiority of the iron for efficiency in the discharge of a Leyden jar. Our result is quite such as might have been expected from experiments made eight years ago by Lord Rayleigh, and described in his paper "On the Self-Induction and Resistance of Compound Conductors."*

Preliminary Experiments to Find if Subtraction of Water from Air Electrifies it.

BY LORD KELVIN, P.R.S., MAGNUS MACLEAN, M.A., F.R.S.E., AND ALEXANDER GALT, B.SC., F.R.S.E.

Experiments with this object were commenced by one of us in December, 1868, but before any decisive result had been obtained, circumstances rendered a postponement of the investigation necessary. A glass U-tube with vertical branches, each 18in. long and about 1in. bore, with the upper 8in. of one of the branches carefully coated outside and inside with clean shellac varnish, was held fixed by an uninsulated support attached to the upper end of this branch. The other branch was filled with little fragments of pumice soaked in strong pure sulphuric acid or in pure water; and a fine platinum wire, with one end touching the pumice, connected it to the insulated electrode of a quadrant electrometer. A metal cylinder, large enough to surround both branches of the U-tube without touching either, was placed so as to guard the tube from electric influences of surrounding bodies (of which the most disturbing is liable to be the woollen cloth sleeves of the experimenters or observers moving in the neighbourhood). This metal tube was kept in metallic connection with the outside metal case of the quadrant electrometer. The length of the exposed platinum wire between the U-tube and the electrometer was so short that it did not need a metal screen to guard it against irregular influences. An indiarubber tube (metal metallically connected with the guard cylinder would have been better) from an ordinary blow-pipe bellows was connected to the uninsulated end of the U-tube. Air was blown through it steadily for nearly an hour. With the sulphuric pumice in the other branch the electrometer rose in the course of three-quarters of an hour to about nine volts positive. When the pumice was moistened with water instead of sulphuric acid no such effect was observed. The result of the first experiment proves decisively that the passage of the air through the U-tube gave positive electricity to the sulphuric acid, and therefore sent away the dried air with negative electricity. A corresponding experiment with fragments of chloride of calcium instead of sulphuric pumice gave a similar result. In repetition of the experiments, however, it has been noticed that the strong positive electrification of the U-tube seemed to commence somewhat suddenly when a gurgling sound, due to the bubbling of air through free liquid, whether sulphuric acid or chloride of calcium solution, in the bend of the U-tube, began to be heard. We intend to repeat the experiments with arrangements to prevent any bubbling of the air through liquid. We have repeated our original experiment with pumice moistened with water in the insulated U-tube, and with an uninsulated U-tube filled with sulphuric pumice between the bellows and the insulated tube, so that the air entering it is artificially dried. With this arrangement the insulated U-tube was negatively electrified by the blowing of the air through it; but this electrification may have been due to the negative electrification of the dry entering air to be expected from the result of our first experiment. We intend to repeat the experiment with artificially-dried and diselectrified air blown through the U-tube containing pumice moistened with water.

* *Philosophical Magazine*, vol. xxii., 1886, p. 469.

Discussion.

The discussion on these papers was neither lengthy nor convincing. The following took part in it: Profs. Quincke, O. Lodge, FitzGerald, Schuster, S. Thompson, and J. J. Thomson. Perhaps, the most important statement came from **Prof. O. Lodge**, who said under the conditions named in the paper, he should not have formed the same conclusions; he should rather have inferred that the results obtained were due to friction, and ventured to predict that by using a metal tube and filtering the air through cotton wool similar results would not be obtained. **Prof. FitzGerald** suggested getting rid of the chemical action by cooling the tube. **Prof. S. Thompson** mentioned analogous phenomena in the voltaic arc, while **Prof. J. J. Thomson** referred to Prof. Stokes's view that the large raindrops in a thunderstorm were a cause and not a result. **Prof. Schuster** thought the differences observed when air was passed through sulphuric acid and water pointed rather to the same conclusions as those indicated in the paper. He had experimented with artificial clouds, but to obtain satisfactory results it needed much larger clouds than could be obtained. His results were of a negative character. The second paper was briefly discussed by **Lord Rayleigh**, **Prof. O. Lodge**, and **Prof. S. Thompson**, Prof. Lodge explaining further his experiment referred to in the paper and page 336 of his book on lightning conductors.

On the Construction of Delicate Galvanometers.

BY PROF. A. SCHUSTER.

Maxwell has shown how a galvanometer must be wound in order to produce the maximum magnetic field for a given resistance. The present communication is intended to show what the advantage gained would be if the winding, which is theoretically best, could be adopted. Assuming the cavity in which the magnet is suspended to be cylindrical, the sensitiveness of the galvanometer will vary with the square root of the resistance, and inversely as the square root of the radius of the cavity. The smallest angle which can be read without making the system astatic, will also depend on the diameter of the mirror—a point which has been neglected in the construction of some recent galvanometers. Taking the resistance of the galvanometer to be one ohm, the diameter of the cylindrical cavity to be one centimetre, and the width of the reflecting mirror to be also one centimetre, the smallest current which a galvanometer will show with a horizontal force of ·17 is, under different conditions, as follows:

If wound in the theoretically, but possible, way, $1{\cdot}60 \times 10^{-8}$ amperes;

If wound on a bobbin of rectangular section of the best dimensions, the wire being uniform in each layer, but changing from layer to layer so as to give the best possible results, $2{\cdot}00 \times 10^{-8}$ amperes;

If wound on a bobbin of rectangular section with uniform wire, the dimensions of the bobbin being the most favourable, $2{\cdot}14 \times 10^{-8}$ amperes.

The advantage gained by having the winding in the way which is theoretically the best is, therefore, not very marked.

A Special Chronograph.

BY HENRY LEA, M.I.C.E., AND ROBERT BRAGGE.

In his capacity as electric inspector for the city of Birmingham the duty of one of the writers is to test the accuracy of the electric meters used in that city. The test involves an accurate measurement, on the one hand, of the current of electricity passing through the meter, and, on the other hand, of the period of time during which the current of electricity effects a certain number of revolutions of the meter armature. For the electrical measurements he selected a Crompton potentiometer, but as his chronograph was not accurate enough he drew up a specification upon which the English Watch Company built the chronograph exhibited to the meeting. The ideal chronograph is one with a perfectly divided dial, an absolute prompt start, a definite stop at zero, and a continuous or running motion of the hand. The test-room chronograph under notice is not intended for use as a watch; it is purely and simply a micrometer applied to time, and therefore it has only two pointers—one from the centre, giving seconds and their fractions, the other placed halfway between the centre and circumference, showing minutes up to 60. The dial of aluminium, being engine divided, is mechanically perfect; and being of large size, 2½in. of sight, the divisions of 10 to the second are clearly defined. The prompt, absolute start is obtained by dispensing with all intermediate gearing and relying on the main train of wheels impelled by the ordinary mainspring. The starting lever not only releases the balance-wheel, but at the same time

Digitized by Google

by the momentary contact of a light spring blade impels the wheel in the required direction. The absolute stop at the end of an observation is obtained by the frictional contact of the aforesaid spring blade with the edge of the balance-wheel. The absolute stop at zero is obtained by fixing upon the axis of the seconds wheel a collet carrying a blade. Upon the top of the movement there is a lever, which, during the period of an observation, is held back; but when the observation is concluded it is set free by a push of the button, and falls to a point where it crosses the path of the blade already referred to, and stopping the wheels brings about the absolute stop we require. The last thing requisite is for the seconds hand to have a continuous run. Everything tried up to the present has had a tendency to accelerate its rate, and is therefore inadmissible. The lever escapement has been adhered to, and by using hard stone jewellings, and by observing great accuracy in the angles of the pallets, the makers are enabled to double the ordinary number of beats—36,000 instead of 18,000—and although in every beat there are three processes, the whole follow so smoothly that the progression of the hand is practically continuous.

The Most Economical Temperature for Steam-Engine Cylinders; or, Hot v. Cold Walls.

BY BRYAN DONKIN, M.I.C.E.

Summary.—The author calls attention to the important question of the most suitable temperature of cylinder walls to obtain the maximum economy by reducing condensation in steam-cylinders to a minimum. To diminish condensation his experiments prove that it is essential to reduce the difference of temperature between the incoming steam and the cylinder walls. In most cases the cylinder walls are much colder than the steam, and often one-half the weight of steam is condensed during admission. Many experiments show that the nearer the temperature of the cylinder wall is to that of the entering steam the greater is the economy. With walls 40deg. to 60deg. F. colder than the steam, as is often the case, the consumption is greatly increased, owing to the large amount of condensation. On the other hand, the cylinder metal can be made too hot and heat wasted at exhaust. This has also been experimentally proved by the author. The best results in steam economy have been obtained when the temperature of the internal surfaces is a little higher than that of the entering steam. Cylinder walls can be heated in various ways. The most usual is to raise their temperature and that of the covers, by means of boiler steam introduced into the jacket spaces. Another method, and one used a good deal on the Continent, is to work with super-heated steam. This steam has been employed in some cases with advantage in the jackets as well as in the cylinders. Smoke jackets have generally proved a failure. When the jacket is connected to a condenser having a good vacuum, economy of steam is also obtained, but not so much as with steam in the jackets. To secure the maximum economy also, it is important not only to diminish the volume of the clearance spaces, but especially to reduce as much as possible the area of the clearance boundary surfaces. In this way the weight of iron heated and cooled per stroke so many degrees can be materially diminished. The character of the internal surfaces, whether rough from the sand or turned, and their position, horizontal or vertical, have also some influence on the transmission of heat and condensation of steam, as verified by recent trials. Experiments have also shown that the cylinder wall in any working steam-engine is divided thermally into two parts; the outer portion remains at a constant temperature and the inner or periodic portion is heated with each steam, and cooled with each exhaust stroke. The relative proportion of these two parts, or the depth to which the heat penetrates into the metal, depends largely upon the speed of the engine, and on the temperature of the cylinder relatively to that of the entering steam. In a non-jacketed engine, with 1in. cylinder walls, working at 35 revolutions per minute, the depth to which the heat penetrates and fluctuates per stroke is at least about eight to nine millimetres from the internal surface. The depth of heat penetration for the same speed is much less with hot than with cold walls; a less weight of metal is heated per stroke, and condensation is found to be much reduced. The author gives some of the results of 80 experiments on a small vertical engine, with cylinder 6in. diameter and 8in. stroke, made expressly for experimental research. The details are to be published in the *Proceedings* of the Institution of Mechanical Engineers. The engine was worked with very different temperatures of walls, and many tests were made, condensing and non-condensing, jacketed and non-jacketed, single and double acting, at different expansions, and with both saturated and superheated steam in the cylinder and jackets. Care was taken in these experiments only to vary one set of conditions at a time. Results of two experiments are added, one with hot and the other with cold walls, or one with steam and the other with air in the jackets. Both tests were made condensing, double-acting, with 50lb. steam pressure, 3-16 cut-off, and at a speed of 220 revolutions per minute. The walls were some 30deg. F. hotter with than without steam in the jackets; the steam consumption per indicated horse-power hour was reduced from 41¼lb. to 28⅓lb., or about 31 per cent.; the thermal efficiency was increased from 5·7 to 8·1 per cent., or 40 per cent.; and the rate of initial condensation was reduced from 460lb. to 217lb. per square foot per hour, or by more than one-half. The percentage of steam present in the mixture during expansion was also increased by about 50 per cent. Throughout these experiments an increase of economy with the hotter walls was always verified; the thermal efficiency was higher, the initial condensation less, and the percentage of steam present during expansion always increased. The tests on this engine point to the practical conclusion that the range of steam temperature in the cylinder per stroke has much less effect on the steam consumption than the temperature of the walls. The paper may be shortly summarised thus: The most uneconomical results were always obtained with the cylinder walls colder than the entering steam. Under these conditions considerable initial condensation was produced, drops of all sizes up to 3mm. diameter being formed and running down the cold surfaces. The heat also penetrated into the colder walls to a considerable depth, a certain quantity being given up by the steam at every stroke, to raise the temperature of the internal surfaces after exposure to the condenser temperature. Both at cut-off and release there was a great deal of water in the cylinder compared with the weight of steam present. On the other hand, the most economical results were always obtained when the cylinder walls were at about the same temperature as that of the entering steam. Under these conditions the rate of initial condensation was very much lower, and the drops of water formed much smaller in size. The heat penetration into the walls was also much less, a smaller amount of steam sufficing to heat the internal surfaces after being cooled by the condenser. The percentage of steam present in the mixture, at cut-off and release, was also very much increased. If engineers and others using steam-engines wish to work economically and with smaller boilers, they must arrange to keep their boilers and covers as hot as the steam entering the cylinder; otherwise the cylinder becomes unintentionally an efficient condenser, with a large area of cooling surface. Properly applied steam-jackets are economical, because they raise the temperature of the walls touched by the steam. Those who cannot steam-jacket the whole cylinder should at least jacket the two covers, which are the most important surfaces. Well-arranged jackets with properly-sized pipes for entering steam and exit water, without places for air to collect, are an excellent investment, and pay a good interest on the small additional cost.

On Engineering Laboratory Instruments and their Calibration.

BY DAVID S. CAPPER, M.A., PROFESSOR OF MECHANICAL ENGINEERING, KING'S COLLEGE, LONDON.

The reliance to be placed upon observations made with measuring instruments evidently depends primarily upon the accuracy with which those instruments record. Neglect of this fundamental truth often leads to inaccurate and erroneous deductions from experiments which are themselves of the highest scientific value; not infrequently the whole value of observations may be destroyed by insufficient care in the calibration of the instruments used. The subject is therefore one of some importance. The author describes the chief sources of error in some of the most common engineering investigations and their probable value, and points out some of the possible methods of correction where such exist. For example, in engine trials there are many possible sources of error. Most of these may be reduced in percentage value by continuing the trial for a sufficient period. But this is not the case with errors which may occur in the indicators, gauges, or spring balances used in the determination of power. In these, unless properly calibrated before trial, very serious errors may be introduced, amounting in some cases to 5 and 6 per cent. of the total power indicated. It is therefore absurd, even if proper precautions have been taken, to rely upon horse-power measurements to two places of decimals. Similarly with regard to tension and compression experiments with standard 10in. bars. Here calibration of the testing machine is extremely difficult, and can in general only be carried out over a small portion of the range of the experiments. Deductions have therefore to be made from the less to the greater, with the result that small errors in the calibration will tend to be magnified. Vertical testing machines have fewer sources of error, and can be calibrated with more certainty, than horizontal machines. Extensometers are, however, much more easily applied to a horizontal bar than a vertical, and variable jockey weights, which are requisite if the same accuracy is to be maintained at low loads as at high, are also more readily adapted to horizontal machines. Extensometers can be made and calibrated well up to the accuracy of the testing machine. With standard bars and a measuring instrument true to the ten-thousandth of an inch, the modulus can be relied upon to the

Digitized by Google

second significant figure. It is doubtful if more can be obtained without very special construction and calibration of the testing machine. The difficulty in bending experiments, again, lies in the accurate application of load. Unless the beams are very short, or of unmanageable cross-sections, the load measurement must be very delicate if readings approaching the accuracy of those in tension are to be obtained. It is possible that some of the discrepancies in published beam experiments may be due to this cause. The paper deals shortly with other cases where calibration is specially needed, to which the limits of this abstract do not permit a more extensive allusion.

Lighthouse Apparatus and Lighthouse Administration in 1894.

BY J. KENWARD, F.S.A., LIGHTHOUSE ENGINEER.

The writer referred to the principles that govern the establishment of modern lights, and described the chief forms of apparatus now best available for the optical engineer—*e.g.*, the single-flashing or the group-flashing holophotal revolving; the fixed and occulting; the lenticular revolving, having refracting centres alone, extended to high vertical angles; and the quick-flashing lights of recent French types called *feux-éclairs*. He compared the dimensions or "orders" of various apparatus, and the radiants of gas, oil, and electricity, and discussed the question of fog in relation to these. He called attention to the need of good ship-lights on the dioptric system, having equality of power in the beam. He suggested certain reforms in lighthouse administration and in lighthouse statistics. The paper was illustrated by drawings, photographs, and tables.

The Electrolytic Methods of Quantitative Analysis

Report of the Committee, consisting of Prof. J. EMERSON REYNOLDS (chairman), Dr. C. A. KOHN (secretary), Prof. P. FRANKLAND, Prof. F. CLOWES, Dr. HUGH MARSHALL, Mr. A. E. FLETCHER, Mr. D. H. NAGEL, Mr. T. TURNER, and Mr. J. B. COLEMAN.

The first work undertaken by the committee has been the compilation of the bibliography of the subject, with which some progress has been made. In addition, the plan on which the experimental part of the work is to be carried out has been arranged. This is to include the investigation of the methods for the determination of the following metals: silver, lead, mercury, bismuth, cadmium, tin, antimony, iron, zinc, manganese; and subsequently of the methods for the separation of these metals both from one another and from other metals. This is all the committee undertook to do when they were appointed without a grant of money. They now ask to be reappointed, and with a grant of £40.

SIGNALLING THROUGH SPACE.*

BY W. H. PREECE, C.B., F.R.S., ETC.

Whenever an electric current rises or falls in a circuit another current is simultaneously induced in every neighbouring conductor, if it form part of a circuit and be separated from the former by some insulating medium or dielectric, such as air. This secondary current flows only during the period of rise or of fall of the primary current.

Hence, if the primary current rises, falls, or changes its direction regularly and repeatedly a given number of times per second, the induced secondary currents will alternate with the same regularity and frequency. The intensity of these secondary or induced currents, among other things, will depend upon the character, form, and direction of the circuits, and upon the distance which separates them from each other. That such secondary currents, or electromagnetic disturbances, as they are called, existed has, of course, been known since the days of Faraday; but that they could be observed, measured, and utilised at a distance of some miles from the primary circuit was not suspected before the introduction of that marvellous, sensitive instrument—the telephone.

When these disturbances are rhythmic, musical sounds are produced in telephones fixed in the secondary circuits, but when they are irregular unpleasant noises alone are heard. If the sounds are preconcerted and directed, like the dots and dashes of the Morse code, then telegraphy is possible, and we have a means of signalling through space without wires. The distance to which we can signal is limited only by the distance to which these electromagnetic disturbances, in their transit through space, retain sufficient energy to actuate our apparatus. The ether is supposed to be the real medium of transmission, and not the air. The disturbances through the ether take the form of undulations or waves, and in character they are similar to those radiations which at other frequencies gives us heat, light, and photography. They move with the same velocity; they are subject to the same operations of reflection and refraction; and they differ only in the number excited per second.

Thus, to deal with the subject of signalling through space we must have a primary conductor in which alternating electric currents can be excited at will. They must alternate with a frequency that will pleasantly affect the ear—say, about 600 per second. They must be manipulated so as to produce preconcerted signals. The primary circuit must be freely exposed in the ether, and the secondary circuit, which it is desired to excite, must not be screened from the primary by means of magnetic or conducting matter. The object of this lengthened enquiry has been to determine the best form of primary and secondary circuit, the function performed by the earth as a part of the circuit, and the distance to which communication is possible with the ordinary practical means at our disposal.

The telephone as an instrument of precision is scarcely sufficiently appreciated. The ear can be trained by its aid to measure graduations of sound as accurately as the eye determines the calibrations of engraved scales. In Hughes's induction balance we have a well-determined absolute zero of silence, and there are many well-defined nodes of sound which may be taken as fiducial points in a telephonic scale. The limit of speech where articulate sounds cease to be comprehensible is one, the limit of Morse signals where telegraphic reading becomes impossible is another. It is quite easy to determine the similar intensity of two sounds, as in photometry the eye determines the similar intensity of two illuminations. The ear, however, requires to be educated, and it is subject to fatigue; but when properly trained, and when assisted by the telephone, it can be used to observe effects with as much reliability as the eye.

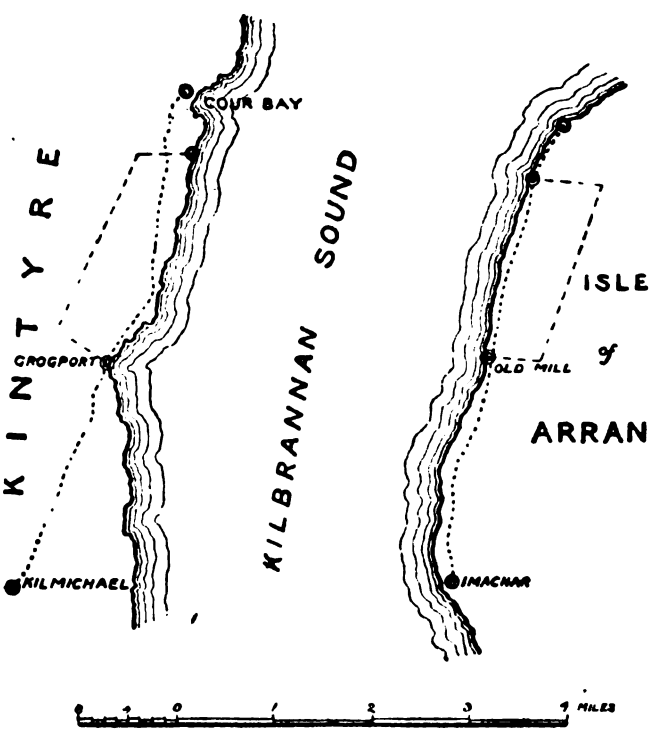

FIG 1.

My attention was first directed to the subject in 1884. In 1886 I brought it before this association at Birmingham, and again at Manchester in 1887. In August, 1893, I reviewed, before the Electrical Congress at Chicago, the whole of my previous nine years' work. Much experimental work has been done during the past 12 months. In 1884 electromagnetic disturbances were detected between telegraph circuits and telephone circuits 80ft. apart, the former in the streets underground in London, and the latter on the housetops; but in 1885 these effects were perceptible between parallel lines of telegraph 10¼ miles apart. The permeability of stone walls and buildings to electric waves was shown by Henry in 1842, when the discharges of a Leyden jar in the top floor of his house induced sparks in a circuit in the cellar. Sonorous vibrations were reproduced in a telephone circuit in the basement of the G.P.O. in 1886 by the induction of a primary circuit excited by the voice in the upper corridor, 80ft. away. Speech was found possible between insulated coils of wire a quarter of a mile apart. Telegrams in 1893 were transmitted across a distance of 31 miles on the Bristol Channel. Regular communication was held last winter across Loch Ness, a distance of 1¼ miles, and recently at a much greater distance, between Arran and Kintyre, across Kilbrannan Sound. Across Loch Ness speech was maintained.

But this is not all. There is every reason to believe that

* Paper read before the British Association at Oxford.

Digitized by Google

we have detected distinct disturbances in our telegraphic circuits due to great electrical storms in the sun's photosphere 92,000,000 miles away.

The fact that these signals across space are effects of induction, transmitted through the air or the ether as the dielectric, is beyond the region of doubt, for they were produced between isolated and insulated coils, each forming a complete metallic circuit; but the part played by the earth at short distances when the earth was used to complete the circuit was not so clear. Very exhaustive experiments were made on the sands in the Conway estuary in 1893, and again at Frodsham on the estuary of the Dee in 1894. These experiments were conducted for me by Mr. Gavey and Mr. H. R. Kempe. Further experiments were made by Mr. Gavey and Mr. Cooper on opposite sides of Loch Ness, a distance of 1¼ miles, and between the Island of Arran and Kintyre, where parallel wires four and five miles apart were available for use.

In the Conway estuary and at Frodsham, squares and rectangles were formed of insulated wires, and numerous measurements were made, both with reflecting galvanometers and with telephones, of the effects due to varying currents in the primaries, and at varying distances between these and the secondaries.

At Loch Ness two parallel wires on opposite sides of the loch were taken. Between Arran and Kintyre, Fig. 1, two parallel lines on opposite sides of the Sound, and four miles apart, were taken; and, in addition, two guttapercha wires were laid along each coast at a height of 500ft. above the sea-level, and five miles apart horizontally.

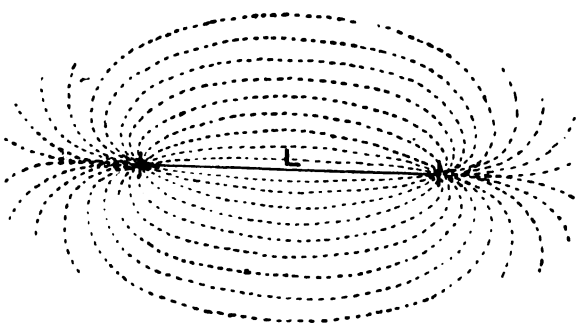

FIG. 2.

The general results and the conclusions arrived at may be briefly summed up as follows: The earth acts simply as a conductor, and *per se* it is a very poor conductor, deriving its conducting property principally, and often solely, from the moisture it contains. On the other hand, the resistance of the "earth" between the two earth-plates of a good circuit is practically nothing. Hence it follows that the mass of earth which forms the return portion of a circuit must be very great, for we know by Ohm's law that the resistance of a circuit increases with its specific resistance and length, and diminishes with its sectional area. Now, if the material forming the "earth" portion of the circuit were, like the sea, homogeneous, the current-flow between the earth-plates would follow innumerable but definite stream lines, which, if traced and plotted out, would form a hemispheroid. These lines of current have been traced and measured. A horizontal plan on the surface of the "earth" is of the form illustrated in Fig. 2, while a vertical section through the "earth" is of the form shown in Fig. 3.

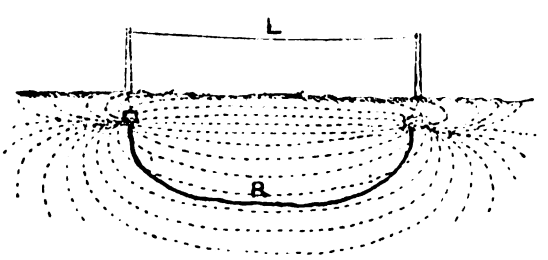

FIG. 3

With earth-plates 1,200 yards apart these currents have been found on the surface at a distance of half a mile behind each plate, and in a line joining the two transversely they are evident at a similar distance at right angles to this line.

Now this hemispheroidal mass could be replaced electrically by a resultant conductor, R, Fig. 3, of a definite form and position; and in considering the inductive action between two circuits having earth returns, it is necessary to estimate the position of this imaginary conductor. This was the object of the experiments at Frodsham.

If the material of the earth be variable and dry the hemispheroid must become very much deformed and the section very irregular, the lines of current-flow must spread out further, but the principle is the same, and there must be a resultant return. The general result of the experiments at Frodsham indicate that the depth of the resultant earth was 300ft., while those at Conway are comparable with a depth of 350ft.* In the case of Frodsham the primary coil had a length of 300ft., while at Conway the length was 1,320ft. At Loch Ness and between Arran and Kintyre, where the parallel lines varied from two to four miles, the calculated depth was found to be about 900ft. The depth of this resultant must therefore increase with the distance separating the earth-plates, and this renders it possible to communicate by induction from parallel wires over much longer distances than would otherwise be possible.

The first and obvious mode of communicating across space is by means of coils of wire opposed to each other in the way familiar to us through the researches of Henry and Faraday. All my illustrations of the principles involved in effecting this object have consisted in opposing two similar coils of wire having many turns, the one coil forming the primary circuit and the other coil the secondary circuit.

Vibratory or alternating currents of considerable frequency were sent through the primary circuit, and the induced secondary currents were detected by the sound or note they made on a telephone fixed in the secondary circuit.

The distance to which the effective field formed by a coil extends increases with the diameter of the coil more than with the number of turns of wire upon it. A single wire stretched across the surface of the earth, forming part of a circuit completed by the earth, is a single coil, of which the lower part is formed by the resultant earth return, and the distance to which its influence extends depends upon the height of the wire above the ground, and the depth of this resultant earth.

Obviously in establishing communication by means of induction there are three dispositions of circuit available—viz. (*a*) single parallel wires to earth at each extremity; (*b*) parallel coils of one or more turns; (*c*) coils of one or more turns placed horizontally and in the same plane.

The best practical results are obtained with the first arrangement, more especially if the conformation of the earth admits of the wires being carried to a considerable height above the sea, whilst the earth-plates are at the sea-level. By adopting this course the size of the coil is practically enlarged, and even if it be necessary to increase the distance between the parallel wires to effect this object the result is still more beneficial. In a single-wire circuit we have the full effect of electrostatic and electromagnetic induction, as well as the benefit of any earth conduction, but in closed coils we have only the electromagnetic effects to utilise.

In one experiment two wires of a definite length were first made up into two coils forming metallic circuits, then uncoiled and joined up as straight lines opposed to each other, with the circuit completed by earth. The inductive effects, and the distance between which they were observable, was very many times greater with the latter than with the former arrangement.

Incidentally some extremely interesting effects of electromagnetic resonance were observed during the experiments in Arran. A metallic circuit was formed partly of the insulated wire 500ft. above the sea-level, and partly of the ordinary line wire on the water-level, the rectangle being two miles long and 500ft. high. Wires on neighbouring poles, at right angles to the shorter side of the rectangle, although disconnected at both ends, took up the vibrations, and it was possible to read all that was signalled on a telephone placed midway in the disconnected circuit.

I have not succeeded in determining satisfactorily the general law which regulates the distance to which one can speak, and I scarcely hope to do so. There are so many disturbing elements introduced, geological as well as electrical. In practice we have to deal with two complete circuits of unknown shape and in different planes. We have obtained some remarkably concordant and accurate results in one locality, but we have met with equally discordant results in another locality. I fear we are beyond the reach of the mathematician. In the appendix I have shown the formulæ that gave the most reliable results.

The mechanism of the mode of signalling across space is not difficult to follow. Its analogue is a flash of light seen at a distance. Energy is expended, say, in a lighthouse on some dangerous rock, or in a gun firing some warning signal, or in a bonfire on some mountain top. The energy assumes the luminous form exciting the ether to undulate with a frequency of many millions per second, which, acting upon the retina of the eye, produce the sensation called light. The burning of the oil lamp of the lighthouse is the primary source of energy; the rapid undulations of the ether propagated in straight lines at a velocity of 186,000 miles per second are the radiation, transmitting this energy in a wave form to the distant ship; the eye is the apparatus which transforms the energy of the light-waves into a form which excites consciousness in the brain.

In our electrical experiments the primary energy is in the current form, the comparatively few alternations per second excite waves in the ether of a few hundreds per second only. But these oscillations of the ether or electric waves are of the

* These figures are obtained from the use of the formula $Q = K\left\{\log\left(\frac{l^2}{d^2}+1\right)\right\}$ which is given in Appendix I.

Digitized by Google

same character as those of light, they move with the same velocity, and when they fall on a sympathetic secondary conductor, they excite in that conductor currents of electricity of the same frequency; and if a telephone be inserted in that circuit and applied to the ear, sounds and musical notes are distinctly heard, which, by preconcerted measures, such as the use of the Morse code, can be utilised for the transmission of messages. Thus messages were sent across the Bristol Channel between Penarth and Flat Holm Island, 3·1 miles away. Speech was maintained in the Highlands across Loch Ness, 1¼ miles broad, and telegrams were transmitted from Kintyre to Arran, across distances of four and five miles, and thus we could readily communicate between England and France, or between outlying islands and the shore, when the conditions admit of the erection of the necessary circuits.

A somewhat fascinating branch of this subject is the possibility of signalling across planetary space. Signalling between one planet and another is merely a question of degree. Magnetic storms and earth currents have some intimate connection with the sun, although Lord Kelvin has questioned the reality of the fact. The great storms and sun spots of March 30 and 31, 1894, were accompanied by very marked and peculiar sounds in telephones inserted in our long telegraph circuits. The storm of July 20 was not so distinguished. Strange, mysterious, weirdlike sounds are frequently heard on long lines of telegraph in the calm stillness of the night, but whether due to terrestrial or to cosmic causes remains to be discovered. The sun's photosphere, when disturbed by spots, may be subject to violent electrical storms, and those vast clouds of incandescent hydrogen that flame up with terrible velocity may excite electrical oscillations through etherial space of such a frequency as to influence our terrestrial circuits. We may thus hear on earth the electric storms of the sun. But this is mere speculation, and the evidence before us at present is not sufficient to justify positive deduction. We shall continue to watch and record, and it is hoped that observers in other parts of the world will assist by making use of the telephones and telegraph lines at their disposal.

The practicability of this method of effecting communication is now solved, but the subject possesses great scientific interest from the views it imparts of the mechanical character of electrical waves, of the molecular theory of electricity, and of the great distances at which electromagnetic disturbances are perceptible.

Appendix I.

The following are the formulæ on which the foregoing calculations are based:

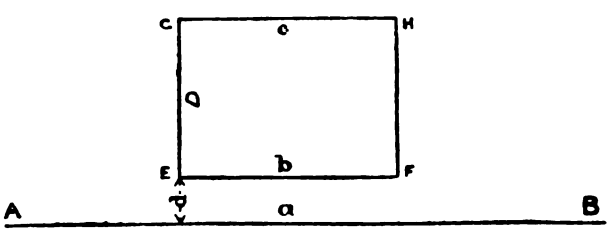

Fig. 4.

Let A B (a), Fig. 4, be an infinitely long wire, and b and c be two wires forming parallel sides of a rectangular circuit, E F G H; then, if a current be set up in A B, the lines of force cutting E F and G H will cause a momentary current to be set up in the rectangle, so that

$$Q = K\{\log (D+d) - \log d\} = K \log \frac{D+d}{d},$$

where Q is the quantity induced.

K is a constant depending on the length of the sides G H, E F of the rectangle in centimetres, the current strength in amperes in the wire A B, and the total resistance in ohms of the rectangle.

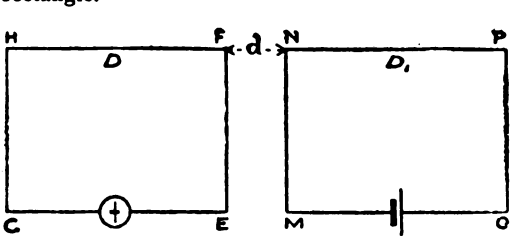

Fig. 5.

Within certain limits this formula is approximately correct even if the wire A B is not infinitely long, but makes one face of a second rectangle similar in form to the induced rectangle E F G H, and set either in the same plane with, or at right angles to, the first rectangle; but in such cases the formula has to be corrected to allow for the influence of the second face of the inducing rectangle as follows.

With two rectangles in the same plane, Fig. 5, the total effect produced by the two faces, M N, O P, of the inducing rectangle is

$$Q_1 = K\left\{\log \frac{D+d}{d} - \log \frac{D_1+d+D}{D_1+d}\right\}.$$

If the two rectangles are at right angles to each other, Fig. 6, and l is large compared with D, then the formula becomes

$$Q_2 = K\left\{\log \frac{D+d}{d} - \tfrac{1}{2}\log \frac{D_1^2+(D+d)^2}{D_1^2+d^2}\right\}.$$

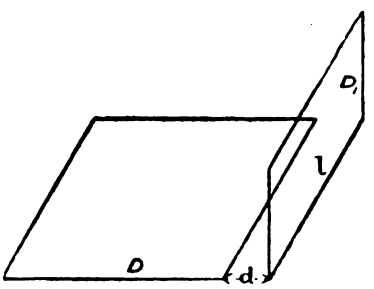

Fig 6

Again, if the two rectangles are parallel and equal, Fig. 7, and l is large compared with D, then

$$Q_3 = K\left\{\log\left(\frac{D^2}{d^2} + l\right)\right\}.$$

These formulæ take into account the effects on the wires in the secondaries which are parallel to the primaries, but not the effects of those at right angles to them. The latter oppose the main induced current, so that in practice this current diminishes more rapidly with the distance than the log law indicates.

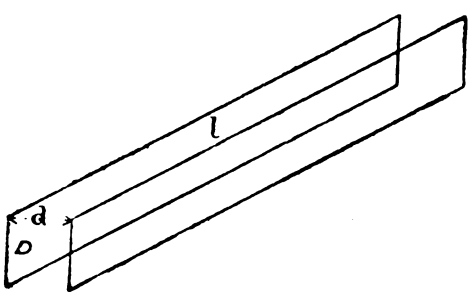

Fig. 7

The problem is very intricate, but Mr. Kempe, to whom I am indebted for the formulæ, still hopes to obtain a final and accurate solution.

Appendix II.

The following letter appeared in *Nature*, April 12, 1894:

Earth Currents.

The Astronomer Royal was kind enough to show me the permanent photographic records of earth currents during the great magnetic storm on February 20-21, and they indicated so unmistakably such rapid and violent alternations that I supplied our principal relay stations with telephones, and with instructions to insert them in circuit whenever they observed indications of disturbances. This happened on March 30-31, during the display of the aurora borealis. Mr. Donnithorne, in Llanfair P.O., Anglesea, reports: "At 2 a.m. (Saturday) the telephone receiver was again tried, and then 'twangs' were heard as if stretched wire had been struck, and a whistling sound. The strength of the earth current was 17·7 milliamperes." Mr. Miles, in Lowestoft, reports: "Noise on 408 (Liverpool-Hamburg) wire seemed like that heard when a flywheel is rapidly revolving," and "sounds in telephone appear like heavy carts rumbling in the distance." Mr. Scaife, in Haverfordwest, reports: "March 31, 2.5 a.m. Earth currents on all wires; wires completely stopped. . . . Peculiar and weird sounds distinctly perceived, some highly-pitched, musical notes, others resembling murmur of waves on a distant beach. . . . The musical sounds would very much resemble those emitted by a number of sirens driven at first slowly, then increased until a 'screech' is produced, then again dying away. Duration of each averaged about 20 seconds." These experienced observers, situated at three distant points, and perfectly acquainted with the ordinary inductive disturbances on telephone circuits, simultaneously observed and independently recorded their own impressions of peculiar sounds exerted in telephones by very rapid alternations or pulsations of currents which accompanied or were consequent on sun spots, earth currents, and the aurora borealis. W. H. Preece.

THE HUNTING OF GOVERNED ENGINES.*

BY JAMES SWINBURNE, M.I.C.E.

Lord Rayleigh pointed out some years ago† that the ordinary explanation of the action of the electromagnet in an electrically-driven tuning fork is incorrect, and that such a mechanism works in virtue of the self-induction of the electromagnet. As far as the action of the contact goes, it is the same whether the leg of the fork is receding from the magnet or approaching it; and if the force depended only on the contact, and was symmetrical, no power would be supplied to the system. It would be like a pendulum which is acted upon by gravity equally whether the bob is going up or coming down. To make the pendulum work continuously, gravity would have to act more when the bob was coming down. As this cannot be arranged a clock has to do the work instead. In the case of Lord Rayleigh's tuning fork, the magnet pulls harder when the leg is coming towards it than when receding, and thus gives power to the fork. In other words, the effect of the magnet lags, and thus becomes unsymmetrical. This is a most important principle, and it applies to a large number of varied cases of great importance, and of more interest to engineers than even electrically-driven tuning forks. Broadly speaking, all kinds of continued vibration may be said to depend on this principle. Among these cases is that of the hunting of governed engines.

If a governor really behaved as it does in most text-books, and admitted steam in exact accordance with the speed of the engine, there would be no such hunting; but, unfortunately, a governor does not follow the variations of speed instantaneously. Apart altogether from questions of friction or movement of heavy valve or expansion gears, many forms of governor, especially what may be described as the relay kind, alter the steam admission with some delay. The friction of the various parts and their tendency to remain in one position until the disturbing force comes up to a certain value, and to then move suddenly and overshoot the mark, increases this action. The result of this time lag in the action of governers is that in many cases engines, especially on light loads, get into a state of vibration known as hunting.

The orthodox way of treating such a subject would be to begin with the discussion of an engine with a flywheel and a frictionless governor with a dashpot or something of the sort, following a simple law. A system might thus be imagined which would fit a differential equation such as that used to find the current when an electrical condenser is discharged through an inductive circuit; and it might be possible to calculate the load which would just prevent permanent hunting, or any hunting at all. There are immense difficulties, however, for there are so many small causes of disturbance that such treatment would probably give no useful information. It may be best, therefore, to discuss the question verbally only, without expecting to arrive at very definite results.

When the load of an engine varies, for instance, by decreasing, if the steam supply remains the same, the extra energy goes to increasing the speed of the flywheel. Whether the speed of the engine follows the steam supply quickly or not thus depends on the flywheel. It also depends on the load. If 1,000 h.p. is working at full load, and 900 h.p. is suddenly thrown off, and the governor does not act instantly, 900 h.p. is devoted to increasing the velocity of the flywheel, and unless the wheel has an enormous moment of inertia, or is turning very quickly, this power will increase its speed, say, 2 per cent. in a very short time. On the other hand, if the engine is only doing 100 h.p., and this load is suddenly reduced to 10 h.p., there is only 90 h.p. to increase the speed of the flywheel, and to increase it 2 per cent. will take 10 times as long as in the former case. Putting the matter the other way, the engine obeys variations of steam supply more slowly at light loads, or, in other words, it obeys its governor more tardily at light loads. In practice, many engines which run steadily at full load hunt terribly when worked light.

Turn now to the governor. It is generally treated as complete in itself, without reference to the flywheel or engine load. A simple Watt governor and most of the governors on small engines have no appreciable time lag, except a certain sticking, due to friction, or to the absurd practice of putting a comparatively small governor to work direct on to a heavy expansion gear, or a stiff stuffing-box. These matters have been discussed in an able paper by Ransom‡ recently. There is not very much tendency to hunting with such governors. Their drawback is that as the steam must be nearly shut off at no load, and full on at full load, the valve gear must be in different positions, and the governor must, therefore, be in different positions too. This means that the engine will be governed at a considerably higher speed at light loads. To cure this the obvious course is to make the governor isochronous. The drawback to this is that an ordinary isochronous governor is not powerful enough if it has to move through a long range with a very small percentage of speed variation. It is likely to stick until the speed has varied a good deal, and then to move to its fullest extent. The result of this would be that the engine would be governed by having full steam and none at all alternately. I do not know why this method of governing should not be employed. If the governor works some light gear, such as the various modifications of the Corliss, this form of governor should work very well with a large flywheel. The cylinder would either get a charge of steam which would correspond to the full engine load, and which would, therefore, be expanded and worked in an economical way, or it would get none. This alternation of full load and no load is common in gas-engines, and, for distinction, may be called the hit-and-miss method of governing. The only steam-engine I know which employs it is the Parsons steam-turbine. Of course, the great difficulty is the flywheel, especially in a slow-speed engine. If working at a tenth of its load it gets steam only every tenth revolution, and the flywheel must carry it round for nine. As high speeds are gradually coming in, it may be worth while to keep this method of government in mind, as it is most economical of steam, and as there is no time lag in the governor, there is no hunting.

Returning to the isochronous governor, the obvious method of overcoming the friction or weight of valve gear is to use some relay—to use a convenient electrical expression. The governor does not then act directly on the valve gear, but puts some screw or other mechanism into gear, which works the expansion or throttle valve. Willans used a water relay. The governor worked a minute water-valve, controlling a cylinder which worked the throttle valve. Such an arrangement can be made very accurate, as a very small movement of the governor, opposed by a very slight force, can be made to work the most obstinate valve gear. But we have at once danger from hunting, as there is considerable time lag in the governor. Suppose the load is suddenly decreased, the engine speeds up and the governor begins to increase the expansion, but effects this slowly, and by the time the valves are right for the reduced load the engine is much above speed. The governor, therefore, goes on reducing the steam until the engine has far too little. It therefore slows down again. But the governor continues reducing the steam until the engine is slowed down to its normal speed. By that time the engine has far too little steam, so it goes on falling in speed. The governor then begins to turn on steam again, but it does it so slowly that the engine has fallen far below speed before the normal steam supply is given, and the governor goes on turning up steam till the engine arrives at its normal speed, when it has far too much steam and is again rapidly increasing in speed. This cycle of operations is repeated over and over again. It depends on the lag of the governor, the flywheel, and the load, whether the hunting is temporary, so that the variations of speed are less and less every time; or permanent, in which case the engine alternates between no steam and, perhaps, full supply. An engine which hunts permanently at very light loads often works perfectly over half-load.

An ordinary governor is thus apt to be insensitive and to allow the speed to vary with the load if designed not to hunt; and if arranged to work a relay, hunting results. An isochronous governor with a dashpot has, of course, a time lag too.

It is easy to make a governor which combines the advantages of both systems and avoids the drawbacks.

A governor made by Messrs. Weyher, Richemond, and Co., of Pontin, may be cited as a good example. It is not isochronous, and it works directly on the steam control. I may mention that even in small engines the French arrange the valve gear so that it is very easily controlled. The variable detent is very common. In addition to working the steam control direct, any movement of the balls from the normal position puts a screw gear into motion, which slowly alters the intermediate gear, so that the engine finally runs at the normal speed, whatever the load is. It is unnecessary to describe the particular gear employed; a typical case may be imagined. Suppose the expansion link is in connection with the middle of a lever, and the governor with one end, the other end being fixed; an increase of speed raises the first-mentioned end of the lever and the middle, and you have an ordinary non-isochronous governor which gives a higher speed at light loads. Suppose, however, that any rise of the first-stated end of the lever sets a train to work which slowly raises the other end, it will go on till the governor is in its normal position. We thus get a governor which does not hunt, and gives the same speed at all loads. If the valve gear is heavy or stiff, the governor may work one end of the lever by means of a relay, but it must be a following relay, such as those employed in steam steering gear, so that the extent, as well as the direction of the movement of the governor end of the lever, is controlled by the position of the governor, and this gear should act as promptly as possible to avoid hunting. The other, or relay gear, then works slowly. In such a governor it will be seen that the first-mentioned end of the lever eventually comes to its normal position in all cases, and only moves to counteract sudden variations of speed. The real control is effected by the slow-moving relay moving the other end.

Instead of using one governor, a pair may be employed, one of which works direct on the valve gear, and the other by means of a slow-working relay. This method does not seem so simple as using a simple governor to do both.

These matters must have been worked out thoroughly by many engineers, and they appear so simple that one almost feels ashamed to bring them forward here, but in looking the matter up I find the governor is generally treated by itself, without reference to the engine. I have, therefore, thought it might be worth while to bring this subject forward, and trust you will bear with me for having put it in such a very elementary manner.

ELECTRIC LIGHTING OF ECCLES.

A report on this subject was recently presented to the Town Council by Dr. J. Hopkinson.

In the course of the report it is stated that the site for the generating plant—very near to the district which the order requires the Corporation to light—is a proper one. For a small station like Eccles would require there would be a very great advantage in the use of accumulators. It followed of necessity that the system must be that with a continuous current. As high a pressure as can conveniently be employed should be used, as thereby the expense of conductors is diminished. This is effected by the three-wire system. For the supply of consumers under the order, exclusive of the lighting of the streets, he advised the use of two Willans or similar engines, each of 100 i.h.p., and each driving its own dynamo, and two locomotive boilers, each competent to supply steam for one engine. One of these boilers and engines would be ordinarily at work, and the others spare in case of accident to the first. The boiler and engine would run each night for one shift, and during the time of working would charge the accumulators whilst the demand for electricity was small, and would supply current to the consumers with the assistance of the accumulators when the demand was large. The accumulators would supply current to consumers at all times when the engines were standing, so that the supply would be absolutely continuous for the whole of the 24 hours. The engines should be provided with condensers, and as there is no means of obtaining a cheap supply of water on the site, means must be provided for cooling the water used for condensation. This can be done in a simple and compact manner, effecting a considerable economy of steam, and will diminish the nuisance caused by throwing the steam directly out into the atmosphere. One set of boiler, engine, and dyname will be capable of supplying a maximum of about 60 units, to which must be added the supply obtainable from the accumulators, an additional 30 units, making in all 90 units. The borough is supplied with gas from an outside source, and therefore has no interest in maintaining any branch of the gas consumption. Dr. Hopkinson understood that the supply of gas for the street lamps cost £890 per annum, and that the wages of the lighters amount to £380 per annum. He had made an estimate of the additional cost to the borough of lighting the whole of the streets. The estimate was not an estimate of the cost of lighting the streets irrespective of carrying on a supply for domestic purposes, but it was an estimate of how much the cost of the electric light station would be increased if the duty of lighting the streets in addition to maintaining the domestic supply were thrown upon it. In preparing the estimate he had the advantage of having recently carried out a scheme of lighting in the borough of Whitehaven. In that town the conditions were very similar to those of Eccles. The estimates proceeded on the assumption that the whole of lights of the borough are replaced by electric lights, and that the power of these lights is a little, but not much, in excess of the present gaslights. The supply would be effected by precisely similar machinery to that which would be used for the supply of ordinary consumers, and the result would be substantially the same as that which has been attained in Whitehaven. He strongly advised the Corporation to undertake the lighting of their streets by electricity. If the remoter district can still be lighted by gas, he should only light those nearest to the station, but if the supply of gas from Salford were cut off he should undertake the lighting of the whole of the streets by electricity. By doing this they could make quite certain that the loss, if there were a loss, would be materially diminished, and a profit, if there were a profit, would be materially increased. Without the street-lighting it is quite possible that the demand for current in the borough would be exceedingly small, and that although the actual cost in running the station would not be considerable, yet it would give a bad proportion between receipts and expenditure. If the street-lighting is added to the scheme they might be certain that even if the light were hardly taken up at all by the general public the actual loss in working, after paying interest and sinking fund, would be very small, and the percentage, when reckoned upon the running expenses of the station, would be quite insignificant, and that a very small demand from the general public would serve to obliterate the loss and show a profit.

Dr. Hopkinson's estimate for the supply of private consumers is as follows: Capital outlay—buildings, with space for more boilers and engines, £1,500; two locomotives, each for 100 i.h.p., with feed pumps and steam water-pipes, £1,160; two "Willans" engines, with condensers and water-cooling apparatus, two dynamos erected, £2,140; accumulators, £800; switchboards and instruments, £250; conductors, £1,500; total, £7,350; engineering and legal expenses, sundries and contingencies, £735; making £8,085. Running charges—wages, £350; cost, £100; water and stores, £25; maintenance of accumulators, £80; maintenance of machinery, £200; interest and sinking fund at 6 per cent., £486; total £1,241. Receipts from one engine, 300 anperes plus 200 volts, equal to 60 units; from accumulator, 30 units; total, 90. Say, 60 units for 800 hours, at 6d. per unit, 1,200. Note.—Sixty units will light 1,000 16-c.p. lamps for one hour. Additional charges for supply of street lights: capital outlay—conductors in street, with lamps and fittings, but exclusive of lamp-posts, £6,000; one boiler, with pumps, pipes, etc., £580; one engine, with condenser and dynamo, £1,070; switchboard, £50; total, £7,700. Engineering and legal expenses, sundries, and contingencies, at 10 per cent., £770; grand total, £8,470. Running charges—wages, £50; coal, £100; water and stoves, £25; maintenance of machinery, £100; interest and sinking fund at 6 per cent., £510; total, £785. Receipts—lighting street lamps, £1,270; less lamp removals, £170; £1,100. With regard to the estimate of the receipts by sale of current, the report states that it is impossible to say with certainty either that the estimate of demand would be reached or doubled. It was therefore an exceedingly doubtful one. The estimates for capital outlay, for running charges, and receipts from street-lighting could be trusted pretty closely, and it would be seen that they left a balance, after paying the interest on sinking fund, of just over £300.

ELECTRIC LIGHTING AT HARROW.

It is difficult to understand why any hesitation should arise on the part of the Harrow Local Board in finally deciding upon an electric lighting scheme. As long ago as October of last year, a report on the subject of introducing a supply of electricity was prepared for the Board by Mr. W. C. C. Hawtayne, of 3, Princes-mansions, Victoria-street, S.W. According to this report, the capacity of the proposed station would be 4,440 10-c.p. lamps; the expenditure on the undertaking, £11,600; and the annual working expenses, labour and supervision, and depreciation, £2,092 Already promises for the lighting of the schools and other premises have been received to the extent of some 3,000 lamps, so that there is no necessity for delay or hesitation in bringing the matter to a successful issue. Some criticism has been passed by Mr. Saunders, Mr. King, and Mr. Howard on the figures given by Mr. Hawtayne in regard to the working cost, etc., the former asserting that instead of £2,092, the amount would be much higher. In this connection, Mr. Hawtayne, in the course of a letter to the Local Board, says:

"I have looked through the figures put before you by Mr. Saunders with reference to the Harrow electric lighting scheme, and can only say that I consider he is entirely wrong. He appears to have submitted my figures to Mr. King, of the Electric Power Storage Company, and to a Mr. Howard, a resident in Harrow, and both these gentlemen have furnished him with counter figures, but it is very evident that neither Mr. King nor Mr. Howard have troubled to prepare independent estimates, but have contented themselves by adopting the most extraordinary unprofessional course of pulling to pieces the report presented by me without having given a moment's thought to the conditions which obtain at Harrow on the size and nature of the undertaking. This is shown from the fact that they question nothing in my report till they come to the question of 'working cost.' This section is divided into three heads—viz., materials, labour and supervision, and maintenance and depreciation. Under the heading of 'materials,' they have accepted all my figures with the exception of that amount estimated for 'oil, waste, etc.' This sum they have doubled without any apparent cause, and in direct opposition to the actual ascertained working cost shown by the returns published by all the principal electric lighting stations in the kingdom. Under the heading 'labour and supervision,' I find that Mr. King proposes to saddle the small undertaking, such as this, with the services of a manager and assistant manager. He also proposes to pay his engine-drivers 42s. per week, and his stokers 35s. per week. Now, Mr. King knows perfectly well that he would never think of paying this rate of wages, and anyone with any knowledge of Harrow will wonder what work the manager and assistant manager could possibly find to do. The average amount paid at Bradford, Brighton, St. Pancras, Hull, Manchester, and Dublin (where the local authority owns the works) in wages, etc., amounts to 0·99 of 1d. per unit delivered to the consumers. I have allowed 1·35d. per unit for Harrow, so as to be well on the safe side, but Mr. King and Mr. Howard are going to pay 2d. per unit, or more than double the amount that any other local authority pays. Under the heading 'maintenance and depreciation' Mr. King remains dumb, but Mr. Howard steps nobly to the front, and without giving any details of how he arrives at his figures he just nearly doubles my figures. He cares nothing about the published returns from other similar undertakings. He evidently wishes to just wipe out my estimated revenue account of £2,950 by showing the annual working cost at £2,990. Mr. Saunders, without any apology for his previous mistake, has, I see, now come down to a more reasonable figure for the repayment of the loans. One word, in conclusion, as to street-lighting by incandescent lamps. Mr. Saunders assures us that wherever they have been tried they have proved a failure, and instances Basinghall-street, London. Two or three streets in the City were lit by incandescent lamps by way of experiment, but the light is no good for such a locality. At each end of

Digitized by Google

Basinghall-street are streets brilliantly lit by arc lamps of 2,000 c.p. each, and to come from one of these streets into Basinghall-street one naturally regards the incandescent lamps of the latter street as a failure. In comparison with the arc lamp, the incandescent lamp is of course a failure, but by itself it is doing street-lighting in many towns in the kingdom, and is an unqualified success in country towns and scattered districts such as Harrow. The following are a few amongst many towns that have been using incandescent lamps for some time now: Chelmsford, Weybridge, Whitehaven, Windermere, Prescot, and there are many others that I cannot call to mind at the moment."

The Harrow Local Board on Thursday of last week instructed Mr. Hawtayne to apply to six firms for tenders for the construction and maintenance of an electric light station in Harrow. Mr. Hawtayne is now getting out a specification, and tenders for the work will then be invited, when it is to be hoped a final decision will be arrived at.

SUBMARINE CABLES AND TELEPHONES.

We are glad to note that the *Pall Mall Gazette* has raised its voice on the questions of cables and telephones. The following extracts from our contemporary are to the point:

Roughly speaking, the cable system of the world belongs to, or is controlled by, a group of British shareholders, who have entrusted the management of their property and interests to Sir John Pender, M.P. Sir John is a man of consummate ability, and has made the fortunes of those who appointed him. On reference to a map, it will be seen that from the offices of the Eastern Telegraph Company (of which he is chairman), in Old Broad-street, he is in telegraphic communication with every important British possession. His company, and its subject or allied companies, charge us what they like for a cablegram to India, the East, Australia, and South Africa, and have powerful influence over the tariff to America. The shortest message to Australia costs from £2 to £3, and a single message has been known to cost £1,400; while the shares of the companies have paid as much as 14 per cent. It is obvious, therefore, that a poor man has no more chance of using the cable to communicate with his emigrant son or daughter than he has of riding a blood horse in the park or of being elected a member of the Royal Yacht Club. There are no degrees in impossibility. A few rich men use the cables sparingly for their private affairs, but the messages are mainly sent by merchants, who, of course, recoup themselves by making their customers pay higher prices, while a smaller but growing number of despatches is exchanged between the Home and Colonial Governments, at the expense of the taxpayers.

In one year our Indian and Australian trade has been compelled to contribute as much as £400,000 to the profits of the companies. The evils of monopolies are always the same, and supply Socialistic teachers with delightfully "shocking examples." The monopolist is not to blame, any more than the possessor of any other kind of property. The real offender is the statesman who confers or confirms the right to hold property under conditions which are injurious to the interests of the State. There are two methods of rectifying the mistake thus committed. The first is that of introducing competition. On this principle the Ottawa conference has sanctioned the construction of an alternative cable to Australia, running across the Pacific from Vancouver. The second, and as we hold preferable, plan is that the Home and Colonial Governments should combine to buy out the companies. It is estimated that the capital required would not exceed £30,000,000, and with such security, and the certainty of cheap cabling in the bargain, the amount would be subscribed in the City a dozen times over. Any morning, in fact, we may wake up and find that Lord Rothschild—repeating his Suez Canal *coup*—has lent Sir William Harcourt the sum required for the operation. In any case, the high tariff system is doomed. Within two or three years, instead of paying 4s. a word to India, 4s. 9d. to Australia, 8s. 11d. to the Cape, and 12s. 2d. to British Guiana, we shall probably have a uniform charge of 6d. a word to Egypt, India, the East, Canada, and other colonies equally distant, and 1s. a word to Australia and South America.

The question of securing the telephones for the nation is one of the gravest moment; and, unfortunately, it has to be decided at a time when men's minds are absorbed in political controversy. The state of affairs is shortly this: one association, the National Telephone Company, owns nearly all the wires and exchanges in the towns, and transacts 95 per cent. of the business. The Post Office has rival telephones, but attracts little custom, and finds its revenue from telegraphs rapidly declining. It has, therefore, persuaded the Government to set aside a million for the purpose of buying the existing trunk lines (of the company) connecting various towns, and of constructing new trunk lines. As has been pointed out, this will be a worse bargain than was entered into on purchasing the telegraphs. All the remunerative business will be left to the company, while the Government will pick up the bones which the company flings to it The profit of telephony, as of telegraphy, or postage, or any other business is made in the large centres of population, and this profit the Post Office ought to secure for the benefit of the taxpayers. If the company (or companies) did the work well and cheaply, there would be less to complain of. But by the confession of the chairman of the National Telephone Company, this is not the case. He admits that the service is defective, and lays the blame on the owners of property, who will not facilitate the necessary works of construction and repair. While private monopolies are concerned there will always be friction and defective service. The obvious duty of the Government is to assert its monopoly for the public benefit, and acquire the property of the companies before its constant development shall make the cost prohibitive. In place of paying from £12 to £20 a year, the charge for a private telephone should not exceed £3 to £5 a year. In the Australian cities of Melbourne, Adelaide, and Sydney telephones are in the hands of the Government, and the charge in Adelaide is only £6 a year to subscribers.

THE GOVERNMENT AND THE TELEPHONE COMPANIES.

SUMMARY OF THE DRAFT AGREEMENT.

A copy of a memorandum of the Postmaster-General, dated 7th August, 1894, setting forth agreements (in draft) with the National Telephone Company, Limited, and the New Telephone Company, Limited, to give effect to the heads of arrangement signed in August, 1894, has this week been issued as a parliamentary paper. We extract the following from the memorandum:

"(1) On the 27th May, 1892, there was presented to Parliament a copy of a Treasury minute describing certain proposals which had been adopted by her Majesty's late Government for the development of the telephone system of the United Kingdom. (2) Amongst the proposals was one that the telephone companies should connect their exchanges with post offices, to enable their subscribers to telephone messages for transmission over the public telegraphs, or through the post as letters, or for delivery as express letters, and to obtain the services of messengers, or the use of the trunk telephone wires of the State. It was also proposed that the companies 'should abandon their right to construct trunk wires, and that the Post Office should purchase from them such as they had already erected, and that in addition to this the Post Office should gradually provide additional trunk wires, so that there may ultimately be a complete system of communication between all the important towns in the kingdom.' (3) To enable the Post Office to carry out the scheme a Bill was introduced, and on the 3rd June, 1892, it was read a second time and referred to a select committee. The committee reported the Bill to the House on the 16th June. At the same time they submitted a special report, in which they expressed the opinion that the responsibility for the details of the agreement for the purchase of the trunk lines of the telephone companies must rest with the Government, but they thought that the agreement should be laid before Parliament. (4) The Bill, after amendment, passed both Houses, and on the 28th June, 1892, it received the Royal assent. (5) On the 11th August in the same year heads of arrangement were signed by Sir James Fergusson on behalf of her Majesty's Government, by Mr. J. S. Forbes on behalf of the National Telephone Company, and by his Grace the late Duke of Marlborough on behalf of the New Telephone Company. (6) After protracted negotiations draft agreements to give effect to these heads of arrangement have now been settled. (7) The Stanhope Telephone Company will surrender their license, with an endorsement under the seal of the company."

The draft of the proposed agreement first refers to the license granted to the National Telephone Company on January 1, 1881, for 31 years, and to the works which the company were empowered to undertake. It then proceeds: "It has been agreed between the Postmaster-General and the company that the company shall sell and the Postmaster-General shall buy certain of the company's telegraphs hereinafter more particularly specified. During the preliminary negotiations for this agreement it was agreed that the purchase-money to be paid for such telegraphs should be the cost price thereof, as shown by the company's books, together with the further sum (in respect of cost of administration) of 10 per cent. of the amount of such cost price, such cost price to be settled by arbitration if the parties differed. As the company's books do not show in detail the cost price of such telegraphs, it has been further agreed between the Postmaster-General and the company that the purchase-money to be paid for such telegraphs shall be a sum equal to the estimated cost thereof to the company (including in such cost all reasonable incidental expenditure), together with such further sum as aforesaid of 10 per cent. of the amount of such cost, and that such estimated cost shall be ascertained by two experts in telegraphic engineering, one to be appointed by the Postmaster-General and the other to be appointed by the company, and that all differences between such experts shall be settled by arbitration in a summary manner upon the respective statements of such experts *viva voce* or in writing, or upon such other materials as the arbitrator may require, but without the aid of counsel."

Passing on from the definition of various words and expressions, the draft agreement continues: "On the first day of July, 1895, or on such earlier day as may be fixed by agreement between the Postmaster-General and the company (which day is hereinafter referred to as 'the appointed day'), the company shall deliver and hand over to the Postmaster-General: (i.) so much of any trunk line erected, or in course of erection by the company on the 11th of August, 1892, as is situate outside any exchange area; (ii.) with regard to those parts of trunk lines erected, or in course of erection, as aforesaid, which are situate inside exchange areas: (*a*) all trunk wires forming part of such trunk lines; (*b*) all posts, cables, tubes, or other works supporting or containing trunk wires alone; (*c*) where the posts, cables, tubes, or other works supporting or containing trunk wires, also support or contain other wires of the company, all such posts, cables, tubes, or other works as support or contain a larger number of trunk wires than of other

Digitized by Google

wires of the company, unless the retention of any such work by the company is established to the satisfaction of an arbitrator to be essential to the conduct of the company's business after the appointed day.

"The several trunk lines, trunk wires, and other works hereinbefore specified, together with all estates, interests, rights, powers, and authorities possessed or enjoyed by the company in relation to the maintenance or erection of the same shall on and as from the appointed day become and be deemed to be the property of and vest in the Postmaster-General absolutely for all the estate and interest previously enjoyed there in by the company freed from any charge or incumbrance thereon created by the company, but subject to all wayleaves and other rentals, contracts, and burdens of every kind, subject to which the company hold the same, or which the company have to pay, observe, perform, or bear in connection therewith. Subject to certain provisions, the Postmaster-General shall indemnify and save harmless the company from all such wayleaves, rentals, and burdens as in this article mentioned, and the company will do all such acts as may be necessary to effect a complete delivery and transfer to the Postmaster-General of all such trunk lines, trunk wires, and works as are in this article mentioned, together with all such estates, interests, rights, powers, and authorities as aforesaid.

"Upon delivery of such trunk lines, trunk wires, and works in manner aforesaid the Postmaster-General shall pay to the company the said purchase-money of £——. From and after the appointed day the company shall, so long as it is required by the Postmaster-General so to do, maintain to the reasonable satisfaction of the Postmaster-General all trunk wires of the Postmaster-General which are supported by or contained in any post, cable, tube, or other work which is the property of the company; and the Postmaster-General shall, so long as he is required by the company so to do, maintain to the reasonable satisfaction of the company all wires of the company supported by or contained in any post, cable, tube, or other work which is the property of the Postmaster-General. The Postmaster-General shall pay to the company and the company shall pay to the Postmaster-General, in respect of all wires maintained as aforesaid, yearly sums accruing from day to day at the following rates, that is to say: (*a*) thirty shillings per annum for every mile of wire carried over the roofs of houses; and (*b*) one pound per annum for every mile of wire otherwise carried. Any fraction of a mile over and above a complete number of miles shall be treated as a mile, and the rates herein specified shall be subject to revision on six months' notice from either party at any time after the expiration of five years from the appointed day, and in like manner at any time after the expiration of any period of five years from the day on which any revised rates shall come into operation.

"The Postmaster-Gerneral may at any prescribed post office establish a call office or any exchange of the company, provided that the use of such call office for communications to subscribers to the company's exchange shall be subject to such charges as are for the time being made at other call offices of the company within the same exchange area. The company may on and after the appointed day at any time and from time to time without such request of the Postmaster-General as aforesaid establish call offices at other post offices on certain conditions. Where and so long as telephonic communication is established between an exchange and a prescribed post office the Postmaster-General will receive at such post office from any office on such exchange any telephonic messages for any of the following purposes—that is to say: (*a*) for transmis sion over the postal telegraphs and delivery as as a telegram, or (*b*) for delivery as an express letter, or (*c*) for conveyance and delivery as an ordinary letter, and the company and the Postmaster-General will respectively do all such acts and things as may be necessary to enable such telephonic messages to be received at such post office and to be so transmitted, conveyed, and delivered as aforesaid."

The memorandum also contains the draft agreement with the New Telephone Company, and a reference to the Stanhope Company also to pass into the hands of the Government.

COMPANIES' MEETINGS.

CROMPTON AND CO., LIMITED.

The sixth annual general meeting of this Company was held at Cannon-street Hotel on Monday afternoon, Viscount Emlyn occupying the chair.

The **Chairman**, in moving the adoption of the report of the directors and the accounts, which we printed in our last issue, said that there was a slight reduction in the gross profits as compared with the previous year's working, but there were certain other matters upon which the shareholders could be congratulated, for there was an increase of £22,000 in the turnover. They had also been able, by care, and economy, and watchfulness, to reduce the trading and office expenses by £3,000. The accounts apparently showed a reduction of £4,000 in the item, but that was due to the transfer of certain amounts from one account to another, the actual figure being as stated. The directors hoped that by further economies they would show a still more favourable result. The sum put down for depreciation of plant had increased by £900. This was partly due to an increase in the number of items, and partly to the desire of the directors to be overcautious rather than to err the opposite way. There was an apparent further increase in the item of subsidiary companies, owing mainly to the shares in the Chelmsford Electric Light Company having been transferred from trade debtors' to the investment account. It was also partly owing to the amount of the debentures which had been taken from the Australian Company. This latter item, however, was not permanently in the account, but a temporary investment. The trade debtors' item stood slightly higher; and the stock showed less, but part of this had been transferred to work in hand. With respect to the depreciation of assets, the chairman had explained in January last that for three or four years past no contracts had been made by the Company where they had to take shares or securities in place of cash for work done. During the past year, however, some of the securities previously taken had depreciated, and their directors thought it best that they should stand lower, and that something should be written off these items. Mr. R. E. Crompton and Mr. J. F. Albright, the managing directors, had agreed to relinquish their shares to the extent of the estimated depreciation, which had been written down severely to the amount of £20,000. A special meeting would be held directly to reduce the capital by this amount, another would be held in about a month, and then an application would be made to the Court of Chancery for sanction. The shareholders owed a debt of gratitude to Messrs. Crompton and Albright for their action in this matter. Their manager of works at Chelmsford had resigned, owing to receiving another appointment, and Mr. Brunton had been appointed manager in his place. Last year they thought that the Australian Company had good prospects and was improving, and they had now received orders from them to a considerable amount. According to advices received by the last mail, the contracts practically secured by the Australian Company amounted to about £40,000. They had been subjected to close competition in most departments, but they also had specialities. The arc lamp department had proved quite up to their expectation, and the cooking and heating appliances would probably prove a valuable property. The City Company had opened a showroom at which their stoves and other appliances were exhibited, and the St. Pancras Vestry had sent out circulars recommending the same. He would have been glad to have been able to tell the shareholders that they would have a full dividend. Recourse might have been had to the reserve fund, but the directors thought it best in the interests of the shareholders to pay only a moderate dividend. The Board were thus enabled to increase the sum set aside for contingencies by £1,000, and to carry forward over £1,000 to next year's account. With regard to the proposed issue of new debentures offers had been received for only about £32,000. It was necessary to raise the debentures to place the Company in a good position, as the want of money hampered them in buying in the cheapest markets and in getting reductions on the price of goods. He hoped the shareholders would put the Company on a firmer footing by taking up the debentures, the proposed issue being one of £100,000 4½ per cent. debentures.

Mr. R. E. Crompton seconded the motion, and in doing so confirmed the observations of the chairman as regarded the past and future of the Company. They now had to experience severe competition from new firms who tendered without full knowledge of what they were doing, and thus reduced prices. The period of low prices, based on erroneous estimates, would, however, result in a weeding-out process of the weaker firms, and then they might expect better prices and times. As regarded the change in the management of the works, Mr. Brunton was the best man he could have picked had he had all England to select from, and the manufacturing department was never in better order. He hoped the tendency of prices would be to increase, but if low prices continued the Company were in as good a position to manufacture cheaply as any other firm, and they could obtain a profit when some of their competitors would be unable to do so.

The motion having been adopted, **Mr. R. E. Crompton** moved, and **Mr. Albright** seconded, that a dividend of 3s. per share on the preference shares be paid, which was agreed to.

Mr. Crompton moved, and **Mr. Tufnell** seconded, the re-election of Viscount Emlyn as a director, and **Mr. Tufnell** moved, and **Colonel Gibson** seconded, the re-election of Messrs. J. H. Duncan and Co. as auditors. Both motions were carried.

A special meeting was then held, at which, on the motion of **Lord Emlyn**, seconded by **Mr. H. Osborne**, a resolution was passed that the capital of the Company be reduced from £300,000 to £280,000 by cancelling paid-up capital which has been lost or is unrepresented by available assets, to the extent of £20,000.

LIVERPOOL OVERHEAD RAILWAY.

The twelfth ordinary half-yearly meeting of this Company was held on Tuesday in Liverpool, Sir Wm. B. Forwood presiding.

The **Chairman**, in moving the adoption of the report and statement of accounts, said he was glad to think that the report which the shareholders had before them was of a very satisfactory and encouraging character. During the past half-year the traffic on their line had increased to an extent which ought to give them all great encouragement for the future. As in all new undertakings, it was difficult to get figures for the purposes of comparison. For instance, if they compared the traffic of the past half-year up to the end of June with that of the preceding half-year, they would be comparing the traffic of a summer half-year with the traffic of a winter period, and if they took the winter half-year they would be comparing it with a broken half-year, for the line was opened in the month of April last year. The figures showed that during the half-year ending June 30 they had carried 2,861,437 passengers, as against 2,475,639 in the half-year ending December, 1893, being an increase of 391,000. It was impossible to compare these figures with those of the previous half-year, because it was a

Digitized by Google

broken period; but he had some figures which would give an indication of the increase of traffic at the present time. During the last half-year they carried 15,300 passengers, and during the corresponding period they carried 11,810 per day; and taking the traffic from April 30 to June 30 last year and comparing it with the same period this year, they found the receipts for the former period, nine weeks, to be £5,890, as compared with £8,045 for the corresponding nine weeks this year, showing an increase of £2,155. That was a very gratifying increase, and he was glad to say that since the close of the half-year with which they were dealing the increase in traffic had been kept up. During the six weeks that had elapsed since June 30 they had received £1,100, which he considered as very satisfactory. They opened the Seaforth Sands Station on April 30, and he was glad to say that their traffic from that station had been everything they expected it to be. It was a valuable feeder to the line. During the half-year they had opened two new stations—one at Nelson Dock and the other at Huskisson, the latter being a removal from the Sandon Graving Dock, and next day (Wednesday last) they proposed to open another new station at the Langton Dock, which experience had shown them to be necessary. With these three stations the line would be complete, and he might say that it would be an omnibus line, and that passengers would have no complaint to make on the ground of distance between the stations. It was an arrangement which would be advantageous to both, and to which he looked forward in the hope of a considerable increase in traffic. Turning to the revenue account, he found that they had received for the half-year £20 044. 7s. 6d., showing an increase of £1,696 on the previous half-year. That figure might be disappointing to them seeing the increase in the number of passengers, but the increase was due to the cheap workmen's tickets in the early morning. Coming to the expenditure, they had spent £14,947, being an increase on the corresponding half-year of last year of £1,215. That was made up of two or three items, including £425 on the ventilation of carriages and other alterations; and an additional sum of £878 on traffic expenses, which was largely made up of the cost of the new stations and the cost of running the 22,000 extra miles. They had also had an increase in the rates of £255, and the law charges were somewhat heavier than the previous half-year. On the other hand, they had effected a saving of £910 by taking over the generating station into their own hands. The total receipts were then £20,000, and the working expenses £14,947, leaving £5,097 to be dealt with. They had paid interest of debentures and calls in advance £2,639, leaving £2,457, which, by the addition of the balance from last year of £2,598, gave £5,056 available for dividend. The directors recommend the payment of 5 per cent. dividend on the preference, and 1 per cent. on the ordinary shares, leaving £1,010 to be carried forward. As regards the future, they were fully alive to the importance of the extension of the system, and they wished to see the present undertaking a little further developed. and they would not do anything without obtaining the sanction of the shareholders. He paid a tribute to the work and ability of the engineer, Mr. S. B. Cottrell, and referred to the interest taken in their work by the servants generally. Sir William then moved that the report be adopted, and that the dividends mentioned be declared.

Mr. Richard Hobson seconded, and the motion was agreed to.

Mr. Samuel Stitt moved a vote of thanks to the chairman and directors, which was seconded and carried.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY, LIMITED.

The thirteenth annual meeting of the Birmingham Central Tramways Company, Limited, was held on Wednesday at the Queen's Hotel, Birmingham, Mr. J. Ebbsmith presiding.

The **Chairman**, in moving the adoption of the report, which was given in our last issue, referred to the recent decision of the House of Lords upon what was known as the purchasing clause of the Tramway Act, a decision which was adverse to the contention of the tramway companies affected and favourable to the local authorities. Dealing with the accounts, he said that the new engines referred to at the last meeting had been received and were working admirably. It was satisfactory to find that upon those engines a saving of close upon ¾d. per mile was effected in the consumption of fuel alone, and he was hopeful that the saving would be more marked during next year. They would have need of economy and improved traffic, for a cloud was looming over them in the Balsall Heath district. The horse department was what it had always been—a difficulty, and a blot upon their accounts. In the cable department there had been a most satisfactory increase of working profit. They could not have their profit at both ends, and he was glad to know that the profit on the cable department far outweighed any corresponding loss upon the horse department on the southern routes. The directors were satisfied that the cable line had established such a dominant position in the district that it was no longer fair or reasonable to expect them to maintain for the benefit of a few the system which up to that time had prevailed, and they had discontinued the horse omnibuses, which more or less were actually in competition with their own trams. He was glad to be able to say they might look with confidence to a probable decrease of expenses and increase of profit upon the working accounts during the next year. The electric department was one of mingled difficulty and hope. The shareholders were aware that the Corporation had not met the directors as they had a right to expect in the hope of establishing another and more economical form of traction, but the directors had turned their attention to two alterations of detail in the present system, which gave them distinct reason to believe that the electric department had seen its worst days, and that it would now show a steady if unsatisfactory improvement. He said "unsatisfactory," because he considered it was unsatisfactory that they should be compelled to work that form of traction which could be replaced by one of equal advantage to the public, and much more economical to the Company. He was quite sure if the Corporation had permitted the experiment of overhead lines to be tried in the Bristol-road, the inhabitants of that thoroughfare would in three months have warmly supported a continuance of the system, and the profit to the Company would practically have equalled the loss which they now sustained. The Public Works Committee laid down the conditions that the roads belonged to them, and they would maintain them, but the Company must pay the cost; and yet in the case of the Bristol-road they had actually entered into a contract with an outside commercial firm to maintain the roads at a price which was altogether in excess of the amount which could possibly be spent upon them. Mr. Carruthers Wain's agreement expired at the end of last year. He had done his work of organisation, and done it well.

The motion having been seconded, was, after some discussion, adopted.

On the motion of the **Chairman**, seconded by **Mr. Round**, a dividend of 2½ per cent. was declared on the ordinary shares of the Company.

WATERLOO AND CITY RAILWAY COMPANY.

The Waterloo and City Railway Company held its first half-yearly general meeting last week, under the presidency of Mr. W. S. Portal, in the Board-room at Waterloo Terminus.

The **Chairman**, after affixing the seal of the Company to the register of shareholders, who numbered 475, moved the adoption of the report and accounts. As this was, he said, the first general meeting, there was obviously very little for him to tell them. So far as the Company was concerned, everything was in a very promising way. The construction of the line had been tendered for, the borings were satisfactory, and the line would be completed, according to the evidence of the contractors, in about two years and a half. The agreement between them and the South-Western Railway Company, which was sanctioned by the shareholders in February last, had received the approval of the Railway Commissioners, and the Board of Trade had given the necessary certificate for the payment of interest on capital during the construction of the railway. The construction of the main portion of the line had been entrusted to Messrs. Mowlem, Burt, and Co., whose tender was less than the parliamentary estimate. All the necessary consents from the several public bodies concerned had been obtained, and up to the present time everything was making satisfactory progress Questions relating to the terminal stations in the City and at Waterloo were under consideration. These stations would, however, form the subject of separate contracts.

The motion was seconded by **Lieut.-Colonel Campbell**, and carried.

CONTRACTS FOR ELECTRICAL PLANT.

CONTRACTS OPEN.

Dundee.—Messrs. Urquhart and Small, of 17, Victoria-street, Westminster, S.W., have been authorised by the Dundee Gas Commissioners to invite tenders for contract No. 8, for a steam-engine and dynamo, in connection with the supply of electric light. Copies of the specification and form of tender can be obtained on payment of £1. 1s. (which will be returned to all *bonâ fide* tenderers) from the above-mentioned firm. Tenders will be received by that firm on or before the 30th inst.

Birmingham.—Tenders are invited for the electric lighting of the glasshouses, etc., at the Botanical Gardens, Edgbaston, Birmingham. A copy of the specification may be obtained from Messrs. Henry Lea and Thornbery, 38, Bennett's-hill, Birmingham, on payment of £1. 1s., which will be returned on receipt of a bona fide tender. Tenders must be sent in on or before September 1, 1894, addressed to Prof. Hillhouse, M.A., hon. sec., Birmingham Botanical and Horticultural Society, Botanical Gardens, Edgbaston, Birmingham.

RESULTS OF TENDERS.

Stowmarket (Suffolk).—The tender of Messrs. T. Prentice and Co., of Stowmarket, at £174, has been accepted by the Local Board for lighting the streets of Stowmarket up to May, 1895, and also for lighting the post office clock.

Walthamstow.—The Private Wire and Telephone Installation Company, of 110, Cannon-street, E.C., inform us that they have secured the contract for fitting up the fire alarms in connection with the houses of 13 firemen, for the Walthamstow Local Board. There are six standard street alarms, and the various offices will be connected by telephone.

Altrincham.—The Manchester Edison-Swan Company have received the contract for the supply of the electrical plant, including alternators and transformers, for the Altrincham Electric Supply Company, Limited. The order for the boilers has been placed with Messrs. Tinkers, Limited, of Hyde; that for the engines with Messrs. Browett, Lindley, and Co., Limited, of Patricroft; and that for the buildings with Mr. J. Hamilton, of Altrincham.

Digitized by Google

BUSINESS NOTES.

Cowes.—The Marine Hotel has received an electric light installation.

Ashford (Kent).—The question of introducing the electric light is in abeyance.

Woodbridge.—The Local Board ask for tenders for lighting the town for 12 months.

Western and Brazilian Telegraph Company.—The receipts for the week ended August 10 were £2,219.

Fleetwood.—The Board of Trade has provisionally approved the electric lighting scheme for the district.

Worthing.—The Town Council have resolved to apply to the Board of Trade to license the Council to supply electricity.

Rugby.—A gas-engine of 120 h.p. is to be put down by the electric lighting company in place of that of 100 h.p. now at work.

Whitehaven.—New applications for electric current are being received by the surveyor to the Whitehaven Town and Harbour Trust.

Hawkshead.—The Highway District Board have agreed to an application by Mr. Fowkes to lay an electric cable between Smoothbecks and Sawrey.

Islington.—The Vestry have received a communication from the Board of Trade, enclosing provisional approval of the system oi electric lighting to be adopted in the parish.

City and Guilds of London Institute.—Particulars are given in our advertisement columns of the various examinations for the session 1894-95 in connection with this institute.

Ulverston.—The question of introducing the electric light into this district, to which we have previously had occasion to refer, has been considered by the Local Board in committee.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 12th inst. amounted to £1,257, as compared with £1,138 in the corresponding week of last year.

Telephony.—The Cardiff Chamber of Commerce on Wednesday passed a resolution urging the establishment of direct telephonic connection by Government wires between Cardiff and London.

Brighton.—The manager of the electric light works has reported to the Town Council that the revenue for the half-year just ended amounts to £4,795, against £2,391 for the corresponding period of last year.

Submarine Telegraph Company, Limited.—The directors of this Company recommend a dividend on the ordinary shares at the rate of 8 per cent. per annum, tax free, for the half-year to June 30.

Cornholme.—Messrs. Joshua Smith, Limited, cotton manufacturers, have been altering and improving Frostholme Mill, which is to be lighted throughout by electricity. The work will be carried out by Messrs. J. H. Holmes and Co, of Newcastle.

Windermere.—The clerk to the Local Board has informed them that he has received a further notice from the electric light company, and that he was writing to the Board of Trade about the provisional order. The matter was left in the hands of the clerk.

Dewsbury.—The Town Council have passed an account for £275 in favour of Mark Scott, on account of his contract for the electric lighting station, and one for £1,000 in favour of Messrs. J. and J. Horsfield, on account of contract for boilers for the same place.

Church-Lighting.—An installation of the electric light has just been completed in the Church of St. Martin-on-the-Hill, Scarborough. About 100 lamps are used. The work has been carried out by Messrs. Walker and Hutton, electrical engineers, of Scarborough.

Newcastle.—Messrs. J. H. Holmes and Co. have in hand the contract to fit an electric lighting installation on the premises of Messrs. Galloway, wholesale confectioners, etc., Clayton-street, Newcastle. The installation will consist of 100 lights, supplied by a "Castle" dynamo.

St. Ives (Cornwall).—The St. Ives Town Council on Friday had before them a proposal to purchase the local gasworks, but after a short discussion it was decided to consider the matter more fully in committee. The Council would be better advised to leave the gasworks alone and introduce the electric light.

City and South London Railway.—The receipts of the Company for the week ended August 12 were £897, against £829 for the corresponding week of 1893, or an increase of £68. The total receipts for the current period of the present half-year amount to £5,203, as against £5,066 in the corresponding period of 1893.

Antwerp Telephone and Electrical Works.—Messrs. W. E. Dennis and Co, of 11, Billiter-street, E.C., inform us that they have been appointed sole agents in Great Britain and Ireland for the Antwerp Telephone and Electrical Works (Société Anonyme), Antwerp, manufacturers of telephones and other electrical appliances.

York.—Mr. Edward B. Pym, of Scarborough, has nearly completed an electric light installation throughout Messrs. Cox and Falconer's premises in High Ousegate. The plant consists of a nine-kilowatt machine, driven by a gas-engine, and the number of lights will be 150. This is the first firm to adopt the electric light in York.

Cooking by Electricity.—The landlord of the Imperial Restaurant, Sise and Pancras Lanes, and 38A, Queen Victoria-street, has discarded coal and gas in favour of electrical energy for cooking purposes. The result is in every way satisfactory. Mr. Percival, the lessee, will show his kitchen to those who may wish to see how electricity can be thus utilised.

Interim Dividend Announcement.—The directors of the Charing Cross and Strand Electricity Supply Corporation, Limited, have declared an interim dividend for the half-year ending June 30 at the rate of £4 per cent. per annum on the ordinary share capital of the Corporation (£150,000), and carried forward £1,335, after payment of £5 per cent. per annum on debentures.

Electrical Exhibition at Ealing.—As will be seen by our advertisement columns, the Ealing Local Board will hold an exhibition of electrical appliances in the Victoria Hall, Ealing, commencing on October 3rd, and continuing to the 13th. Manufacturers and others desirous of exhibiting can obtain information respecting same upon application to Mr. C. Jones, C.E, Public Buildings, Ealing, W.

Taunton.—The electrical engineer (Mr. H. W. Cowzens) reported to the Town Council on Tuesday that during the past quarter improvements and alterations at the electric light works, suggested by Dr. Fleming, had been completed. The Electric Lighting Committee reported that they had insured the electric lighting station, machinery, and plant in the Atlas Insurance Office for £6,000 at 4s. per cent.

Leeds Tramways.—The town clerk of Leeds has received notification that the action commenced by the tramways company against the Corporation to recover £61,000, being the difference between the value of the tramways on the structural basis and their value on the rental basis, will not be further proceeded with. This course, it is stated, has been taken in consequence of a recent judgment of the House of Lords.

Ship-Lighting.—The s.s. "Knight Bachelor" has made her trial trip on the Firth of Clyde. For expeditious working of cargo she has seven hatches and seven of Messrs. Clarke, Chapman, and Co.'s steam winches; and when it may be necessary to work at night the vessel is supplied with a cluster of electric lamps to illuminate the decks. The vessel has a complete installation of the electric light carried out by Messrs. J. H. Holmes and Co., of Newcastle.

Bristol.—The Electrical Committee of the Town Council reminded the Council on Tuesday that at their meeting on December 12 they authorised the committee to arrange for the borrowing of the further sum of £24,000 for electric lighting. The sanction of the Local Government Board has now been obtained, and the committee have arranged to borrow the money from the Bank of England. The Council adopted the report of the committee on Tuesday.

Chester.—The Town Council have received a letter from the clerk to the County Council, Mr. Reginald Potts, giving the Corporation the opportunity of buying a portion of the old county gaol site. It appeared that the County Council proposed to lease the land to the War Office, with the exception of the portion offered to the Town Council. The matter, after some discussion, was referred to the Improvement Committee, it being suggested that the site might be a desirable one for the electric light works and the baths.

Stirling.—It was stated at a meeting of the Police Commission on Monday that the Caledonian Electric Supply Company and the House-to House Electric Supply Company had notified to the clerk their intention of applying for a provisional order to light the burgh. It was agreed, on the recommendation of the Electric Light Committee, to meet on the 17th prox. to make arrangements to acquire the order for the town. The area of supply was fixed as the burgh, and the compulsory area as King-street, Murray-place, and Port-street.

Edmondson Electricity Meter Syndicate, Limited.—This Company has been registered with a capital of £2,000 in £1 shares, to take over the patents and patent rights for the manufacture of electricity meters, invented by Mr. Joseph Edmondson, of Bradford, electrical engineer, either alone or in conjunction with Mr. Joseph Oulton, of Bradford, and to manufacture and deal in electricity meters and all apparatus, etc., connected with the measuring of electricity and to carry on the general business of electrical and mechanical engineers.

Blackpool.—The minutes of the Electrical Committee, adopted by the Town Council last week, included particulars of a claim on behalf of Mrs Wild for an alleged accident in Market street, the Corporation disclaiming liability in the matter. The tender of Mr. W. Moister, for the excavating and concreting required for the foundation for the new chimney at the electricity works, was accepted. The recommendation of Mr. R. Hammond, the consulting electrical engineer, that a further sum of £500 be expended in the provision and laying of street mains was adopted.

Monmouth.—With regard to the preliminary expenses in connection with the drainage and electric lighting, Mr. Tippins asked, at a meeting of the Town Council last week, what arrangements had been made for the preliminary expenses before they got their drainage loan. Mr. Mayor replied that the treasurer and himself had waited upon Lloyd's, and had learned that they were willing to grant whatever the Corporation might want before they were in a position to negotiate their loan. He did not think they would want to go over £2,500, including the present overdraft.

Hotel-Lighting.—The ordinary general meeting of the Inns of Court Family Hotel, Holborn, was held last week at the hotel, under the presidency of Sir Edwin Galsworthy, J P., who said that they had extended and would still further extend, the electric

Digitized by Google

lighting installation. Messrs. Rashleigh Phipps and Co., of 102, Oxford-street, have received instructions for the electric lighting of Limmer's Hotel, Conduit-street and George-street, Regent-street. The firm also obtained the contract for the lighting of the Howard Hotel, Norfolk-street, Strand, with 450 lights of 16 c.p.

Bromsgrove.—The Local Board have considered a resolution proposing that the application of Messrs. Hemming and Co., electrical engineers, Birmingham, for the consent of the Board to their laying down plant for electric lighting in the district be granted. Mr. Leadbetter seconded the proposition. Mr. Hall moved an amendment that the question be referred to the committee to consider and report before deciding upon the matter Mr. Weaver proposed that a town's meeting be called to consult the ratepayers. Mr. Hall seconded the amendment, which was carried.

Hoisting Machinery.—Messrs. Pickerings, Limited, of Stockton-on-Tees, inform us that they have appointed Messrs. Bolton, Fane, and Co., of 96 and 98, Leadenhall-street, E C., as their agents in London and district for the sale of their lifts, hoisting, and other machinery. Messrs. Bolton, Fane, and Co. have acquired the old-established business of iron, tinplate, and metal merchants formerly carried on by Messrs. Ben Gibson and Co., and latterly by Messrs. Harry Williams and Co., and in the management of this branch of their business they will be assisted by Mr. Harry Williams.

Newport.—The work of laying the pipes for carrying the electric cables for the central station, which is about to be erected by the Corporation, was commenced on Monday in a section in Dock-street, Newport, between Cross-street and the electric station in Friars'-field. Messrs. Fowler and Co., of Leeds, are the contractors. The Town Council have decided to pay the contractor for the electric light (street work) installation £500 on account of his contract, without keeping him for the proper period of one month longer. This payment, it was provided, should not form a precedent.

Appointments Vacant.—The Corporation of Blackburn invite applications by the 25th inst. for the post of engine and dynamo attendant. Applicants must have had experience of central-valve high-speed engines and dynamos as applied to a three-wire system. Applications, stating age, previous experience, and wages required, with not more than three recent testimonials, are to be addressed to Mr. Robert E. Fox, town clerk, Town Hall, Blackburn. The Corporation also invite applications for the post of central-station wireman; in this case also applications are to be forwarded not later than the 25th inst.

Woking.—The Sanitary and Lighting Committee of the Local Board have reported that the contract for electric lighting had been settled with Mr. New, and was recommended for sealing. It provided for 48 single and 13 double lamps, the price to be reduced if possible, and with iron open shades instead of globes. In reply to Mr. Dalziel, who asked a question as to the distribution of the lamps, Mr. Storey said the distribution was practically the same, except that they had decided to light all the back streets, which were not lighted when the Board took them over. This would mean 13 more lamps. The report was agreed to.

Factory-Lighting.—Messrs. Mardon, Son, and Hall are having the electric light installed in their new factory at Temple Gate, Bristol. The offices and works are being fitted throughout with 500 16 c.p. lamps. Arrangements have been made so as to allow of an addition of another 120 16-c p. lamps if necessary. The current is supplied from an Edison-Hopkinson dynamo, manufactured by Messrs. Mather and Platt, Limited, and has an output of 350 amperes at 105 volts. The whole of the arrangements is being carried out by Mr. E. J. Tongue, consulting engineer, and is under his personal supervision. The contract for the work has been secured by Messrs. F. W. Ball and Co., of Unity-street, College Green.

Radcliffe.—The Electric Lighting Committee of the Local Board decided some time ago that Messrs. R. Walker and S. Walker interview the Earl of Wilton's agent with reference to the purchase of a plot of land in Mount Sion road, the plot having been offered to the Board for a period of 999 years at 1½d. per yard It has now been resolved that Mr. Bennett be requested to inform the committee upon what terms he will provide the plans and estimates for the electric lighting station, plant, and the necessary means and appliances, and give all engineering assistance required up to and inclusive of the obtaining of a provisional order, and to also state his terms for the carrying out of the work from the obtaining of the order to the completion of the work.

New Issue.—W. T. Henley's Telegraph Works Company, Limited, announce that the increase of the company's ordinary business (as distinct from laying submarine cables) and the prospect of extending it in new directions render it advisable to increase the capital. For this purpose it has been resolved to pay off the existing mortgage of £10,000 at 4½ per cent., the £15,000 A debentures at 5 per cent., and the £12,000 B debentures at 6 per cent., and to raise a further sum of £13,000 by the issue of £50,000 debenture stock. This stock will bear interest at 4½ per cent. payable half-yearly, and will be secured by a trust deed constituting a first charge upon the company's property and undertaking, and will be redeemable by the operation of a sinking fund.

Stockton.—At the May meeting of the Stockton Corporation the town clerk was instructed to write to the Board of Trade requesting that the Electric Lighting Order, 1890, might be further extended for a term. He has now received a reply stating that the Board of Trade are not disposed to allow it to remain in force any longer unless the Corporation are prepared to give an undertaking that they will give effect to its provisions within a year from the present time. At a Town Council meeting it was agreed that the Board of Trade should be informed, in reply, that the Corporation will give effect to the provisions of this order within two years from this date. Alderman Hind stated that Alderman Richardson, M.P., had called at the Board of Trade and obtained an intimation that two years would be allowed.

Meeting of Creditors.—The first meeting of the creditors of Mr. M. L. Ross, an electrical engineer, who formerly had offices at 90, Queen street, Cheapside, was held before Mr. Cooper, deputy receiver, at the City Bankruptcy Court last week. The debtor failed about 12 years ago, when carrying on business at Boston, U.S.A. He closed the office at 90, Queen-street in 1892, having lost about £6,000 in the business. Since then he has been engaged in the development and sale of various patents, and he attributes his failure to delay in the completion of certain contracts. He denies that he is insolvent, but does not estimate the value of his assets in his statement of affairs; his debts he returns at £1,954. 10s. The meeting stood over to August 29, at noon, for a scheme of arrangement to be submitted to the creditors and reported upon by the official receiver.

Leicester.—A committee has reported to the Leicester County Council that by the month of October it was expected the Corporation of Leicester would be in a position to supply the electric light at the Assembly Rooms. The committee considered it desirable, if the Council decided to have an installation of electric light, that the wiring of the rooms and the fittings should be attended to before the repairs were carried out. It was estimated that the sum of £250 would be sufficient to meet the cost of wiring and providing suitable fittings for lighting the large room, drawing, dining, and smoking rooms, and the entrance-hall, and the committee recommended the Council to carry out the work. Mr. Bowles, in moving the adoption of the report, expressed the opinion that the committee were following a wise course in recommending the Council to use the electric light in that building. The cost would, he believed, be well within the sum of £250 which was mentioned.

Hertford.—The Lighting Committee of the Town Council have reported that the returns so far received with regard to the adoption of the electric light were encouraging. A full report on the subject was promised as soon as the committee was in possession of the complete returns. In proposing the adoption of the report, Alderman Shelly remarked that it referred to the circular which was sent round to the householders—a method not very well adapted for obtaining precise statistical results, but which was calculated to give some idea of what was the general feeling of the town. He was sorry the complete returns could not be brought before the Council, and he hoped definite information would be ready very soon, because there were indications that if the matter was to be taken up it should be taken up shortly. The returns obtained up to the present were very encouraging, the number of applications being more than treble those received on the former occasion.

Poole.—The Poole and Bournemouth Tramways Company, referring to their application to the Board of Trade to extend the time for the commencement and completion of the Poole and Bournemouth electric tramways, have written to the Dorset County Council that they hoped long ere this to have commenced the works, and would have done so had the times been more propitious. They had, however, now secured the co-operation of some capitalists, who would make an issue of the capital of the company at the earliest possible date, and, in addition, had made arrangements with a large company for laying down the electrical plant, and were negotiating with a firm of contractors to construct the permanent way and erect the necessary buildings. They had had an interview with the Secretary to the Board of Trade, who informed them that before they considered the application they should furnish them with a resolution of the Council consenting to the extension of time being granted. The Council have decided not to grant further time.

Dalkey.—The Dalkey Commissioners have determined on taking proceedings against the tramway company to compel them to put their line in order. A local paper says: "Leaving aside the condition of the tramroad, let us ask what has become of the gigantic scheme to provide an electric tramway from Dublin to Dalkey? The company that is now to be proceeded against promised last year that they would form the electric line. They pointed out the advantages of such a system to the Boards of Commissioners, and asked, if we remember rightly, their countenance to the scheme. We then heard how the townships might be beautifully illuminated by electricity, and we stared in amazement when we had pictured for us rushing trams, cosily appointed and lighted, and driven by the electric current. The change was to have been made last March, but we have as yet heard nothing further about the matter. How is this? Did the directors really intend to form the electric service, or was the promise only a sop thrown out to keep the dogs from howling against the condition of the roads?"

Traction at Bristol.—The ordinary general meeting of the shareholders of the Bristol Tramways and Carriage Company was held at the Grand Hotel, Broad-street, last week, when Mr. W. Butler, J.P., chairman, presided. In the course of his remarks the chairman said: "I am pleased to say that after an inspection of the system of overhead electricity as applied in South Staffordshire, the Corporation and its officials were much impressed with the advantages of the system, and at once admitted that the principle could be satisfactorily applied in Bristol. There were, however, as you may well imagine, a very large number of con-

Digitized by Google

ditions which had to be thoroughly discussed, and upon which we ultimately came to complete agreement. The specifications and drawings for the new electrical tramway are nearly ready, but we have not wholly waited for these, as we some time since ordered the necessary copper wire to lay down a short piece on the old St. George's line, which we shall get the Board of Trade inspector to pass immediately it is completed, so that we may be on safe ground in carrying through the bulk of the construction of the electrical lines."

Brechin.—Dean of Guild Ferguson, convener of the Lighting Committee, at Monday's meeting of Police Commission reported that, in accordance with instructions, the clerk had written to the Northern Electric Lighting Company and the House-to-House Electric Lighting Company asking on what terms they would be prepared to supply electric light to the town. No very definite reply had been got, but some member of the Commission had had an interview with Mr. M'Leod, of the House-to-House Company, who had answered a number of questions, and as he was to be in Brechin again next week the committee proposed meeting him and going over the whole matter. The Clerk, in answer to a question, stated that Mr. M'Leod had written to the effect that his company would supply the electric light at 6d. per Board of Trade unit. A long discussion took place. The Dean of Guild moved that a special meeting of Commission should be called to meet Mr. M'Leod. Mr. Jamieson seconded. Mr. Murray moved, and Mr. Knowles seconded, that Mr. M'Leod be not asked to come to Brechin. Ultimately the finding of the meeting seemed to be that they should not meet Mr. M'Leod as a Board, but that every member who desired should do so.

Southport—The Gas and Electricity Committee of the Town Council have reported that with reference to the electric lighting scheme the Local Government Board have given their consent after holding an enquiry for the land before named being used for electric light purposes, and have also sanctioned the borrowing of £28,000, the same to be repaid within 25 years from the date of borrowing. The laying of the two cables named in the scheduled area, and a little beyond, has been completed, the engines, boilers, and dynamos are all about ready for delivery, and the buildings are approaching completion It is expected that electric current will be ready for consumers before the end of the current year, for which the price has been fixed at the rate of 7d. per Board of Trade unit, the current to be supplied by meter. A number of tables were appended to the report, the consideration of which was deferred. The expenditure on capital account for the financial year 1893-4 includes £1,590. 7s. 10d. for electric light Councillor Travis sai l that the machinery put down was equal to the supply of 4,000 8-c.p. lamps; and quite apart from anything which the Corporation might require for the municipal buildings, they had already received applications for something like 1,800 8-c.p. lamps. The report has been adopted by the Town Council.

Hampstead.—On the motion of Mr. James Thwaites, chairman of the Electric Lighting Committee of the Hampstead Vestry, it was decided that the Electric Lighting Committee be empowered to engage such staff as they may consider necessary for working and attending to the plant at the central electric supply station, and the mains connected therewith. Mr. Thwaites said that Mr. R A. Chattock, the recently appointed chief engineer, would commence his duties on September 3, and it would be necessary that the machinery and mains should be thoroughly tested before October 1. the date fixed for the beginning of the supply. A letter was received from Mr. R. A. Chattock, confirming his acceptance of the appointment of chief electrical engineer to the Vestry, and tendering his thanks to the Vestry for the same. A cheque for £500 was down in payment of the eleventh instalment to Messrs. Yerbury and Sons under the contract for the erection of the central supply station. The third instalment under Messrs. Siemens Bros. and Co.'s contract for supplying and fixing plant amounted to £3,811. 4s, for which a cheque was drawn. The account included the following items: boilers and accessories, £1,499. 12s.; pipes, £400; dynamos and accessories, £1,392; switchboards, etc, £148; arc lamps and posts, etc., £155. 9s.; transformers, £166. 8s. A cheque was also drawn for £75 in payment of commission due to Mr. Preece, C.B, the consulting engineer.

Stowmarket.—A number of gentlemen assembled in the Institute Hall on Wednesday to consider the desirability of introducing the electric light in the town. Mr. C. G. Hayward presided. Many tradesmen of the town and many private residents have expressed a wish to adopt this illuminant. Mr. Charles R. Dewhirst convened the meeting, and Mr. Napier Prentice gave some statistics as regards the cost and maintenance of the light. Figures were given which showed that there was not much difference in cost between electricity and gas. Then came the question of supply. Three methods could be adopted. The first would be to get the gas company, who could do it cheaper than anyone else, to put down a gas-engine and run a dynamo. The second would be to form a company and provide means for generating electricity. The third plan would be to call in an outside company, who would sell the electricity after having obtained a provisional order. Several gentlemen took part in the discussion, Mr. Gostling stating that although a shareholder in three gas companies he was in favour of the electric light. In reply to a question, Mr. Prentice said the cost of fixing incandescent lamps of 16 c.p. would be about 20s. each. Mr. Gower thought that the gas company could doubtless supply the light better than anyone else. On the proposition of Mr. Gostling, seconded by Mr. Gower, the meeting unanimously appointed Mr. Prentice and Mr. C. R. Dewhirst as a committee to approach Messrs. Thos. Prentice, the lessors of the gas company, with a view of inducing them to supply the town with the electric light.

Winchester.—The question of introducing a municipal supply of electricity, to which we referred in our last issue, has again been considered by the Town Council. A report of the Joint Committee of the General Purposes and Electric Lighting Committee, embodying proposals of the gas company and the Brush Electric Lighting Company respectively, was submitted, and it was on this that the discussion took place. The committee recommended that the Council should take steps to obtain a provisional order for the public and private lighting of the city according to the system suggested by the Brush Company. The Mayor (Alderman Stopher) pointed out that the report was incomplete, and he furnished the figures—155 lamps of 16 c.p. for side streets, 142 lamps of 32 c.p. for main streets, and 14 lamps of 50 c.p., with 133 oil lamps as at present costing £2. 5s. each, making a total of £1,020. The ex-Mayor, in moving the adoption of the report, entered at length into the question, pointing out what he considered were the advantages of electricity over gas, and the benefits accruing by the obtaining of a provisional order at a cost of about £250. Other members having expressed their views, Alderman Warren pointed out that all they were asking for was the cost of the provisional order; so as to protect themselves and get the powers in their own hands. It was stated that the cost of procuring the order would amount to £250; and that to carry out the electric lighting scheme it would be necessary to obtain borrowing powers for £25,000. Eventually it was decided to proceed with the application for a provisional order.

Gas and Electricity in London.—A deputation, consisting of representatives of all the North London Vestries, the Holborn District Board of Works, and the Gas Consumers' Protection League, waited on Thursday last week upon Mr. Bryce, President of the Board of Trade, to ask for an enquiry into the metropolitan gas supply. In the course of his reply to the deputation, Mr. Bryce said in regard to the gas companies that he thought Parliament did make a bad bargain, and that it was to be regretted that the hands of Parliament and of London were tied in the way in which they were tied by existing statutes. He was happy to say that the Board of Trade had learned by experience in this matter; and he could also say that the Board would have made a better bargain for the people of London in previous years than had been made for them by Parliamentary Committees. The researches which had been made for him into the archives of what had passed then, showed that the Board of Trade would gladly have done more for the people of London in those days than Parliament permitted it to do. When the question of electric lighting came up—as was no doubt known to the deputation—provisions were inserted in the Electric Lighting Provisional Order Bills, under which the interests of the people of London in the future were protected and provision made for them. It was quite true that great steps forward had been taken since 1876. They had, he thought, much larger views of what was due to the interests of the people than they had in 1876. He was also sure that, if they were entering upon this matter again, they would have the same regard to the interests of the people as was had when the Electric Lighting Bills were passed; and that they would endeavour to profit by the experience which had been obtained since then by those great towns in which the gas supply was in the hands of the municipality.

Profit Sharing.—A report on profit-sharing, undertaken by Mr. D. F. Schloss on behalf of the Labour Department of the Board of Trade, was issued on Monday. In indicating the scope of enquiry, Mr. Schloss states that profit-sharing, as the word is used by him, comprehends a variety of forms of industrial remuneration, all covered by the definition given in the first of the resolutions passed at the International Congress on Profit-Sharing held at Paris in 1889, a meeting which was attended by a large number of the leading exponents of the method. Profit-sharing is there declared to be "a voluntary agreement by virtue of which an employé receives a share, fixed beforehand, in the profits" of an undertaking. The report first deals exhaustively with the share system and with industrial co-operation, and then gives a history of profit-sharing in Great Britain. From the detailed description of the different cases in which profit-sharing has been adopted, it is noted that in hardly two cases is the system adopted identical in all particulars, and the task of classifying the various methods is far from easy. In a certain number of cases (of which Sir Joseph Whitworth and Co., Limited, "A. B.," Willans and Robinson, Limited, William Thomson and Sons, Limited, and Brownfield's Guild-Pottery Society, Limited, may serve as good examples), the right to share in profits accorded to the employés is a strict legal right, the employers being under an express obligation to pay the bonus. But in many cases the bonus is declared to be given "gratuitously." In the cases of Messrs. Willans and Robinson, Limited, and Messrs. Crompton and Co., Limited, the employés holding debentures received a fixed interest of 5 per cent., with the right to a higher rate if the profits exceed 5 per cent. Among cases in which the bonus is a proportion of the entire profits without any reservation of a minimum interest or dividend or reserved limit in favour of the employers, we find 10 per cent. of the amount available for division as profits allotted to the bonus fund by the New Welsh Slate Quarry Company, Limited, and by the Brush Electrical Engineering Company, Limited.

Portsmouth.—The Electric Light Committee of the Town Council recommended that they should be authorised to extend the supply of electricity through Unicorn-road to the Connaught Drill Hall, at an estimated cost of £265, and that application be made to the Local Government Board for their sanction to the

Digitized by Google

borrowing of that sum. The committee also recommended that they be authorised to extend the supply of electricity through Clifton-road, and also along the Clarence-parade as far as the corner of South-parade, at an estimated cost of £1,000, and that application be made to the Local Government Board for their sanction to the borrowing of that sum. In moving the first of these clauses, Alderman Ellis stated that he had had a report prepared, which showed that, exclusive of the public installation, on June 16 last 2,094 16-c.p. lamps were in use in private houses, while the number on August 1 had increased to 3,517 lamps of 16 c.p. He congratulated the Council on this increase. It was a very important matter, since on the day they arrived at 6,000 or 7,000 they would be able to run the installation of the town and pay all expenses without coming on the rates for a farthing. This could only be done by extending their lines and getting people to take up the new illuminant. The number of shops that had taken up the electric light in Russell-street was double the number he had prophesied, and he ventured to say that the amount realised at the end of the year for that district would be nearer £600 than £300. Councillor F. G. Foster said that it should be known that if in any district the support promised would guarantee a return of 6 per cent., the committee would extend their lines in that direction. If, however, it was proposed that the arc lighting at Southsea should be increased, without a proportionate extension of the light to the northern side of the borough, he should strongly oppose it. Alderman Ellis pointed out that the fire brigade station, the police station, and the Corporation stables, and the baths were still lighted by gas. If the various committees would only support the Electric Lighting Committee, it would be much better for that committee and also for the ratepayers. The recommendations were adopted.

The Waterloo and City Railway.—The huge pile of staging in the Thames on the south side of Blackfriars Bridge is the first outward and visible sign of the existence of the Waterloo and City Railway Company. The object is to construct a line from Waterloo to the Mansion House. Messrs. John Mowlem and Co. are the contractors, and the engineers are Messrs. Galbraith and Church. A representative of the *City Press* has gathered some details of the construction of the line, from which it appears that there is a peculiarity in this respect at least, that the above-named staging in the river is the basis of the whole of the operations, and the advantage of this is that there will be no openings on land, and therefore no property to acquire in the streets for carrying on the works, and no interruption to traffic. Within the space enclosed by the timber piles huge cylinders, 16ft. in diameter, will be sunk well into the London clay, but not down to the level of the tunnels—the up and the down—which will be of cast iron, 12ft. in diameter, where the line is straight and on easy curves, but 9in. wider on sharp curves, so as to allow the running round of the bogey carriages to be employed without fouling the sides. Below the cutting-edge of the cylinders brickwork in cement will be used. At the tunnels' levels, shields—two in each cylinder—forced by hydraulic pressure, will be used for boring through the clay, the *débris* being raised to the surface of the river, taken away in barges, and used for levelling, or what not, far away from the scene of operations, for the railway. The precise form of the carriages does not appear to have been decided upon yet. It is anticipated that the journey from end to end will occupy four minutes. The contract was placed on June 1, and the contractors have undertaken to construct the tunnels from Cross-street, Waterloo-road, to the Mansion House in 2½ years. The station works will be separately contracted for. Operations were commenced on June 18, and the sinking of the first cylinder at Blackfriars will be begun in the course of a few days. The resident engineer for the railway is Mr. H. Dalrymple Hay, and for the contractors Mr. W. Rowell. The line will be worked by the London and South-Western Railway Company.

Wolverhampton. — The Wolverhampton Town Council on Monday discussed various points in connection with the electric lighting of the town. In reply to Mr. Weaver, it was stated by Mr. Craddock that the contractor who is laying down the electric light cables in the streets was not liable to replace the foot pavement in the state in which he found it. An allowance was made in his contract for this work which would amply recoup the ratepayers. Replying to Mr. Stevenson, Alderman W. H. Jones stated that Mr. A. P. Brevitt, the architect, was acting as clerk of the works at the electric light works. Mr. Cousins asked when the improvement in Lichfield-street would be completed. Alderman Owen said the committee were waiting for a faculty to be granted before the work could be proceeded with. A discussion was raised by Mr. Stevenson, who drew attention to a letter from Mr. Walton, the secretary to the Wolverhampton Trades and Labour Council, alleging a violation of the fair wages clause contained in the contract relating to the execution of certain work at the electric light station. Mr. Johnson said the matter had been enquired into by the committee, who had come to a conclusion by a large majority that there had been no violation such as was alleged to have taken place. With that decision, however, he disagreed. Mr. Rhodes thought it was a piece of gross impertinence on the part of any section of society to dictate to the Council. Mr. Johnson said the Council had passed a resolution that no portion of a contract should be sub-let, yet work at the electric lighting station had been sub-let without the written consent of the Council. Mr. P. Lewis did not think it right that a resolution of the Council should be allowed to be violated, nor did he think it impertinence for a representative of the working-men to call attention to any violation of a resolution. The report of the committee on the subject was read, and it was stated that it would be impossible to carry on work if they were to quarrel with contractors over trifling matters. Alderman Dickenson said the whole question arose with regard to some work being executed on piecework instead of daywork, and as far as he gathered the wages received were as high as would be paid for daywork. He contended that there had been no sub-letting at all. It was a question whether the work should be executed on piecework or daywork. Mr. Craddock said there was no suggestion that there had been any sweating, or that anyone had suffered through a technical violation of the clause having taken place. On a vote being taken the report was adopted.

Halifax.—Good progress is being made with the Corporation electric light works, and there is every probability, if all continues to go well, that the opening of the works will take place early in November. Three Lancashire boilers, each of 350 h.p., with which a commencement is to be made, have already been fixed, and beds for three dynamos are in course of preparation. Ample provision is being made for extensions in both these departments as the demand for the electric light increases, space having been left for an additional six boilers and for two extra dynamos. For any further extensions some adjacent land near will have to be brought into use. The engines for the driving of the dynamos are being supplied by Messrs. Pollit and Wigzell, of Sowerby Bridge, and they are now almost completed. These, however, will not be delivered, or the dynamos fixed, until the building has been roofed in, a work which is now in hand. The large chimney is being built, and a start has now been made with the reservoir required for condensing purposes. The laying of the cable along the streets was commenced this week, a work that will occupy about three weeks. It is believed that when the plant has been got into complete working order there will be a great demand for the electric light. Already orders for the light have been received from about 70 customers, who will take 2,000 of the 5,000 lights which will be available for private customers from the plant now being put down. Certain banks, large shops, and one or two places of worship will use the electric light. The committee of management of Trinity-road Baptist Chapel have decided to light the chapel throughout with electricity, and have finally adopted the plans and specifications submitted by Messrs. Walter Emmott and Co., who have been entrusted with the work. The body of the chapel will be illuminated by about 109 incandescent lamps suspended from the ceiling and from the under parts of the galleries. The chapel is being repainted and decorated throughout, and it is expected that this, together with the electrical installation, will be completed by October 6. The Halifax Club are also having their premises fitted throughout for about 140 incandescent lamps, and the wiring for this work is just about completed. This has also been entrusted to Messrs. Walter Emmott and Co. The Town Council appointed a sub-committee to consider the desirability or otherwise of lighting the Town Hall electrically. The committee have advised the Council to sanction an expenditure of £500 in furnishing the building throughout with the fittings necessary for an electric light installation. The proposal has, however, been negatived.

Reading.—The Highways Committee of the Town Council have lately reported having received applications from Mr. F. W. Albury, on behalf of the Reading Electric Supply Company, for permission to construct a level railway crossing in Vastern-road, and a transformer sub-station under the cabmen's shelter in the Market-place. The committee recommended that the approval of the application in regard to the transformer station be agreed to subject to the company paying a rent of £20 per annum, but recommended that the other application be rejected. The Town Clerk submitted a draft which had been sent to him by Messrs. A and C. Collins, the solicitors to the Reading Electric Supply Company at the request of Mr. Kite, of a proposed license by the Corporation to the Laing, Wharton, and Down Syndicate, Limited, to assign to the said company all the rights or privileges conferred upon Messrs. Wharton and others by the agreement between them and the Corporation dated March 6, 1889, relating to the fixing of posts, poles, and wires in or over the street in this borough for purposes of the supply of electricity. The committee resolved to recommend to the Council to grant the license applied for, but subject to the provisions of the Reading Electric Supply Order granted by the Board of Trade to the company in respect of this borough and confirmed by the Electric Lighting Confirmation (No. 5) Act, 1893, and upon the understanding that the license shall not be construed as sanctioning the supply of electricity by means of overhead wires except as authorised by the order, or as authorising any particular system of supply, and that the town clerk do settle the draft license accordingly. It was further resolved that the town clerk do forward for approval by the Reading Electric Supply Company, Limited, an agreement between them and the Corporation for providing security to the extent of £1,000 for due payment of any expenses incurred from time to time by the Corporation in executing works which they are empowered or may be required to execute under the provisional order. At a subsequent meeting, Messrs. Collins forwarded a statement of the nominal, issued, and subscribed capital of the company, and urged that as that statement showed that the company could meet any claims the proposed deposit was unnecessary. The committee decided to recommend that the proposed security be £500 instead of £1,000. Mr. Walters moved a resolution to the effect that the application of the Reading Electric Light Supply Company to lay a railway crossing in Vastern-road be granted. He argued that the company was a public one, established for the convenience of the inhabitants, and, further, that it would save the roads if a railway crossing were made. Any future application of a similar nature, he said, could be treated on its merits. Mr. Wellman seconded the motion, which was lost by a large majority.

Digitized by Google

Telephone Wires at Cardiff.—The Public Works Committee of Cardiff considered on Thursday of last week the subject of the institution of a system of underground wires in connection with the National Telephone Company, Limited. A letter was read from Mr. W. E. L. Gaine, of the company's head office, on the matter, and the copy of agreement was forwarded on behalf of the company. The Borough Engineer (Mr. W. Harpur) pointed out that the company, in the agreement they submitted, sought really perpetual powers. There was no question of the termination of the agreement, nor payment for the privilege. The agreement as drafted by the company was practically equal to an Act of Parliament, giving them the right to put down pipes in any and every street in the borough. He could not recommend the committee to accept it. The Post Office people had not such powers. They made application for every pipe put down, though they had the right of appeal to quarter sessions in the case of refusal. The committee instructed the town clerk (Mr. J. L. Wheatley) and the borough engineer to prepare a draft agreement. Mr. Gaine attended before the committee and explained that the company found the work at their two exchanges in Cardiff could not be so efficiently fulfilled as they would desire, and had, therefore recently acquired premises at the corner of New-street by the Custom House Bridge. The company intended to concentrate their Cardiff exchanges in one central exchange. It being necessary to take down a considerable amount of overhead plant, the company deemed it advantageous to ascertain the views of the Municipality on the subject. If the desire was to put the wires underground it would involve greater initial expenditure, though in connection with maintenance he did not know whether underground or overhead wires was the cheaper system. Some discussion took place on the subject of wayleave, and £5 per mile per annum was proposed. Mr. Gaine said the company were quite willing to pay nominal rent, but beyond that he would not go, and he was not prepared to assent to either £5 or £2 per mile of pipes per annum. Unless the rent applied only to the length of streets used this would not be a nominal rent. He would prefer to put down underground pipes, but if they had to pay more than nominal rent he should, in view of the additional cost, not do so. It would cost from £4,000 to £5,000 for overhead wires, and to put the wires underground it would cost £20,000. They had to pay £75,000 to the Post Office to compete, and in Cardiff they fulfilled a great service to the public. Councillor Johnston observed that the company took the profits whereas the Post Office devoted the profits to the nation. Mr. Gaine retired, and the committee appointed the chairman, Mr. Beavan, and Mr. Johnston to confer with the town clerk and borough engineer and arrange an agreement with the company. The committee decided that a rent of £1 per mile per pipe of 3in. diameter should be charged.

PROVISIONAL PATENTS, 1894.

AUGUST 7.

15034. **Improvements in instruments for measuring electric currents.** William Thomson (Baron Kelvin), 154, St. Vincent-street, Glasgow.

15051. **An improved grip to be employed in laying electric cables.** Robert Middlemass, Peasholme House, Scarborough.

15065. **Apparatus for making electrical contact by passage of a railway train.** Edward Tyer, 28, Southampton-buildings, Chancery-lane, London.

15070. **Improvements in overhead conductors for electric railways and tramways.** William John Brewer, 9, Gracechurch-street, London.

15082. **Improvements in magneto-electric machines for cycles or other vehicles and driving gear for the same.** Ernest Tilmann and Charles King Lexow, 22, Southampton-buildings, Chancery-lane, London. (Complete specification.)

AUGUST 8.

15170. **Improvements connected with arc lamps.** John James Rathbone and Arthur Chester, 166, Fleet-street, London.

15174. **An electrical rolling contact making and breaking device.** Karl Ast, 34, Southampton-buildings, Chancery-lane, London. (Complete specification.)

AUGUST 9.

15219. **Improvements in the method of and means for preventing undue reciprocal influences between telephonic lines, or between telephonic and telegraphic or other electrical lines.** Emil Müller, 6, Lord-street, Liverpool. (Complete specification.)

AUGUST 10.

15258. **An improved material for the manufacture of lamp, gas, electric light shades, and other fancy articles.** Harrington O'Reilly, 8, Berners-street, London.

15276. **Improvements in or connected with diaphragms for electrolytic purposes.** Martin Kiliani, Walter Rathenau, Carl Suter, and Elektrochemische Werke Gesellschaft mit beschränkter Haftung, 47, Lincoln's-inn-fields, London. (Complete specification.)

15282. **Improvements in or connected with ploughing by electricity.** Friedrich Brutschke and Hugo Schimpff, 4, South-street, Finsbury, London.

AUGUST 11.

15321. **Improvements in and relating to flexible telephone cords.** Otto Schrimpff and Ruppert Riffelmacher, 70, Market-street, Manchester. (Complete specification.)

15353. **Improvements relating to electric motors.** William Routledge, 4, South-street, Finsbury, London.

15356. **Improved means for opening or closing valves, taps, electric switches, and the like.** Daniel Thomas Bostel, 32, Southampton-buildings, Chancery-lane, London.

15360. **Improvements in arc lamps.** James William Rogers, 24, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1892.

20598*. **Electric accumulators.** Theyryc and Oblasser. (Amended specification.)

1893.

14130. **Electrolysis of iodides, bromides, etc.** Hargreaves and Bird.

14131. **Electrolysis of chlorides, iodides, etc.** Hargreaves and Bird.

15485. **Glow lamps and holders.** Mann and Hopwood.

17197. **Dynamo-electric machinery.** Crompton and Brunton.

17341. **Alternate-current dynamos.** Kapp.

17348 **Electrical transformer street surface boxes.** Bowden and Boby.

17645. **Distribution and regulation of electric current.** Grenfell and March.

17866. **Electric accumulators.** L. W. and G. E. W. Schöffer.

17972. **Electric bells, fire and burglar alarms, etc.** Mills.

1894.

433. **Electric switch.** Elieson.

5572. **Elastic ear-cushion for telephone receivers.** Fearnley.

8218 **Electric signalling.** Jones and Collier.

8585. **Electric conductors.** Conner.

10386. **Clocks for operating electrical alarms.** Fritz.

10851. **Electric railway signals.** Lake. (Beattie.)

11100. **Electric dental motor apparatus.** Denison.

NOTES.

Junior Engineering Society.—The members of this society are visiting Cardiff and neighbourhood during the present week.

Dredger-Lighting.—The large dredger "Percy Sanderson," which has just been launched on the Clyde, is lighted throughout by electricity.

Anarchists and Electricity.—It is announced from Chicago that electrical explosive machines have been discovered in the possession of local Anarchists.

Central Station at Culm.—Good progress is being made with this station, which is being carried out by the Allgemeine Elektricitäts-Gesellschaft of Berlin.

Park-Lighting.—A correspondent of a daily paper suggests that arc lamps should be introduced for the illumination in the evening of the avenues in the public parks.

Electric Traction in France.—As mentioned in a previous issue, the electric tramway at Havre was partly set in operation in July, and this month all the lines have been opened to traffic.

Electric Traction in France.—It is proposed to construct an electric tramway to connect Gérardmer with Retournemer. The electric tramway system at Saint-Adresse has just been opened.

Electric Heating.—It appears that in winter time the electric cars on the Mont Salève electric railway in Switzerland are heated by electricity from resistance coils carried in metallic cases under the seats of the cars.

Electric Tramways for Plymouth.—A local paper urges that horse traction should be abolished at Plymouth, that steam is not to be thought of, that cable traction is expensive, and that electric traction is what is required.

Electric Traction at Baden-Baden.—A special municipal commission is studying the question of building an electric tramway from Lichtenthal to the Rhine. It is estimated that the cost of the line, together with the central station, will amount to about £82,500.

Paris Exhibition of 1900.—In our issue of June 15 we gave the heads of the various sections of this exhibition as far as related to electrical matters. The sub-divisions of the various electrical sections are given at length in the *Bulletin International de l'Electricité* of 20th inst.

Tunnel-Lighting.—The Ivanhoe Tunnel, which is on the point of being completed, is cut through the backbone of the Rocky Mountains from Busk to Ivanhoe. The tunnel is 9,400ft. long. During construction the tunnel was lighted by electricity, an arc light being placed at intervals of 80ft.

Patents, Trade Marks, and Designs.—We have to acknowledge receipt of a copy of "A Practical Treatise on Patents, Trade Marks, and Designs," by Mr. David Fulton, A.M.I.C.E., Fellow of the Chartered Institute of Patent Agents. It is published, at 15s., by Messrs. Jordan and Sons, of 120, Chancery-lane, E.C.

Electrically-Lighted Hansom.—The Gloucester Railway Carriage and Wagon Company have built a hansom cab for Mr. Oscar Farmer, Montpellier-mews, Gloucester, which is lighted electrically. A battery is placed underneath the seat of the driver. The interior light is of 2½ c.p. and the two side lamps outside of 4 c.p.

The Hermite System in India.—Experiments are to be carried out to ascertain whether the Hermite system can be adopted in Bombay. Before going to any expense, *Indian Engineering* advises the Commissioners to communicate with the Singapore Municipality, as Mr. Newton, the assistant municipal engineer, has personally watched this process for disinfecting sewage on behalf of that municipality.

Electro-Chemistry in Austria.—There has been formed in Vienna, under the title of Konsortium für Elektrochemische Industrie, a company having for its object the electrolytic preparation of soda, etc., on the patents of Mr. Kellner, of Hallein, near Salzburg. It is proposed to erect a works at Golling, near Hallein, where water power to the extent of 2,500 h.p. is available, and where raw material can be procured cheaply.

Underground Railways in Paris.—The French Minister of Public Works, M. Louis Barthou, has this week visited London and Liverpool, where he studied the system of metropolitan and tubular railways, with a view to suggesting, on his return, the construction of similar lines in Paris. He was accompanied by several directors of railways and the deputy for the Vosges, who is the reporter before the Chamber on the Berlier project for a tubular electric railway in Paris.

Ageing Brandy Electrically.—According to the annual report of the directors of the Brandy Distillers' Company, Limited, great progress has been made by their technical manager in the ageing of brandy by electricity, which, it is said, will enable the directors to dispose of their brandy at advantageous prices within 18 months after distillation. The process consists of the application of ozonised compressed air to the spirit while it is under the influence of an electric current.

Electrical Communication with Lighthouses.—The Royal Commission on Electrical Communications with Lighthouses and Light-vessels intend to visit Liverpool next week. The following are the members of the Commission: The Earl of Mount-Edgcumbe, the Hon. H. L. Mulholland, M.P., Admiral Sir Leopold M'Clintock, K.C.B., Vice-Admiral Sir George Nares, K.C.B., W. H. Preece, C.B., Sir Edward Birkbeck, J. C. Lamb, and J. A. Kempe. The secretary is Mr. Ernest G. Moggridge.

Gas v. Electricity at Hanley.—A further result of the introduction of a municipal supply of electric light at Hanley is shown by the fact that the British Gaslight Company have decided to reduce the price of gas to private consumers in the Potteries district from 2s. 9d. to 2s. 6d. per thousand. There will also be a reduction in the price charged for public lighting of 5s. per lamp per annum, making the charges £2. 15s. per lamp. This is the second reduction due to the adoption of the electric light.

Telephony in Italy.—The project for the erection of telephone lines between the chief Italian cities is ready. The lines will be: Rome—Naples; Rome—Genoa, Turin; Rome—Florence, Milan; Turin—Milan; Turin—Genoa; Rome—Florence—Venice. It is subsequently intended to construct lines in connection with Paris, Berne, Berlin, Vienna, and Trieste. The Italian Minister of Posts and Telegraphs has decided to send an inspector to Germany to study and report upon the organisation of the telephone service in that country.

Postal Telegraphs.—The annual report of the Postmaster-General, which has just been issued, states that the work of connecting by telegraph the coastguard stations on exposed parts of the coast for the saving of life is now proceeding steadily, some 74 stations having been brought into connection this year. Further, in pursuance of the recommendations of the Royal Commission telegraphs have been extended to 18 of the principal shore lighthouses. Lundy Island, the Goodwin Sands lightship, the Kentish

Digitized by Google

Knock lightship, and the Gunfleet pile lighthouse are now in communication.

Durham College of Science.—This college, the professor of which is Mr. R. L. Weighton, M.A., M.I.N.A., provides complete courses of instruction in mechanical, marine, and electrical engineering, and naval architecture. New buildings for the accommodation of the department have been erected, and the laboratories are equipped with quadruple-expansion engines and boiler for experimental purposes, a 100-ton testing machine, turbo-electric generator, dynamo, horizontal compound engines, etc. The session commences on September 24. Prospectuses can be obtained on application to Mr. H. F. Stockdale, secretary of the college, Newcastle-on-Tyne.

The Trans-African Telegraph.—Sir James Sivewright, who was formerly general manager of telegraphs in the Cape Colony, speaking in the Cape House of Assembly, of which he is a member, on the subject of the Trans-African telegraph line, said there is little to prevent the completion of the telegraph from Capetown to Cairo, but, in his opinion, it could never be a competing line with the cables. Unless some improvement not now foreseen is made in telegraphy, they would never be able to send a message direct the whole distance. The two places are not in the same latitude: they would be going from mid-summer to mid-winter; and the elements would effectually prevent the attainment of their object.

Wellington (New Zealand).—A leading article in a Wellington paper, referring to the lighting of the city, says: "In some parts the lamps make the darkness visible, but they certainly do very little more. This should not be. The present average cost of street-lighting is over £2,000 a year, and the city should get better value for the money than it is now receiving in the dispersion of nightly darkness. If the money is not enough to secure better lighting, then more should be spent in order to save outlay from being largely useless and a waste. With Dr. Lemon to advise it, the Electric Light Committee of the Council should be able to see thoroughly into the whole matter. As things are at present, the lighting of the city is certainly extremely deficient."

Light Railways.—"Progress" has written to a Cork paper as follows: "I have been reading attentively the reports of Irish railways and other companies, and I have come to the following conclusions—1. That the railways ought to be worked and owned by the Government. 2. That corporations ought to take over the lighting of the cities with electric or other form of light. 3. That tramways should be run by the body corporate. 4. That the people should meet and discuss these matters before the general election. I hope that the Mayor will convene a public meeting of the citizens to consider the questions raised. The prosperity of the country is at stake, and the people of the United Kingdom are crying out for cheap railways, cheap light, and cheap tramways."

Electric Mail Cars.—The Atlantic Avenue Railway Company has completed an electric postal car designed by the company's officials, assisted by the postal authorities of Brooklyn, patterned after the standard type of postal car used on steam lines. Only half the car will be used for postal purposes, the other half being a smoking compartment. There are pigeon-holes for distributing the mails, and hooks for holding the mail pouches upon. Drop-letter boxes are provided at each corner of this compartment. The exterior of the car presents a very handsome appearance. It is painted white, like the United States mail cars which are run on steam routes, the smoking compartment being lettered "Smoking Car." The windows are covered with wire screens. Two of these cars have been put into service.

Telephony in Glasgow.—The Telephone Committee of the Town Council last week discussed the Postmaster-General's copy of memorandum with reference to the proposed agreements with the National Telephone Company and the New Telephone Company, and of which we gave an abstract in our last issue. It was pointed out that the Postmaster-General was left absolutely free to grant a license to the Corporation of Glasgow or any other licensee. In reference to communication with towns outside the municipal area, the committee were satisfied that it was absolutely secured that in the event of Corporation telephones being established messages would be taken and delivered in the same way as by the present company.

Dalziel on Telephony and Telegraphy.—We always admire Dalziel's telegrams, and that is the reason for our reproducing the following items published on Wednesday. From Brussels the Dalzielite says: "It has been decided by the Belgian Government to open negotiations with the British Government for the construction of direct telephone communication from London to Brussels *vid* Ostend, it being understood that should the negotiations be successful the authorities at Berlin have signified their willingness to consent to a connecting telephone line from Brussels to Berlin. It is thus highly probable that before long London will be in direct telephone communication with Berlin." From Paris the correspondent states: "It is rumoured here that negotiations are pending between the French Atlantic Cable Company and one of the largest of the English telegraph and cable systems for an amalgamation."

Leipsic Tramways.—Mr. Bayley Hawkins mentioned at a meeting of the Leipsic Tramways Company on Tuesday that it was expected that certain street electric tramways in Leipsic would be worked by a German company, with the sanction of the Municipality, but in the opinion of the company's representatives, and having regard to the experience gained in other towns, no serious competition, he stated, need be apprehended. At the present time the directors had no actual knowledge that concessions had been signed and properly registered, but they believed that there was a determination to have some of these electric lines, and the wisest course to be adopted by the English company in the circumstances was to strengthen their resources in every way they possibly could. That had been done in the present year to a greater extent than it had ever been done before. The information with respect to the concession, which Mr. Hawkins was unable to give, appears in our note on "Electric Traction in Germany" in another column.

The Odessa Central Station.—The extensions of the electricity works at Odessa, which were commenced by Messrs. Ganz and Co. in 1887, have been completed, and the undertaking has now passed into the possession of the Municipality. It appears that the contract was handed over first from one firm to another, resulting eventually in the General Electric Company of New York agreeing to equip the station. The first plant laid down comprises three Thomson-Houston alternators, giving 60 amperes at from 2,080 volts to 2,300 volts, the exciters yielding 30 amperes at 110 volts when driven at 1,450 revolutions a minute. The generators are operated by three compound vertical condensing engines made by Messrs. F. Tosi and Co., and supplied with steam from two boilers made according to the Collet system by the Compagnie Générale des Chaudières Inexplosibles of Paris. Although the works are now owned by the town, as above mentioned, the working of the station has been leased to Messrs. Margulis and Co., of Odessa, who have entrusted the technical management to Mr. Novinsky.

Turning Lathes.—A fourth edition has been issued by the Britannia Company, of Colchester, of the handbook edited by Mr. James Lukin, B.A., entitled "Turning Lathes: A Manual for Technical Schools and Apprentices. A Guide to Turning, Screw-Cutting, Metal-Spinning, Ornamental Turning, etc." The book commences with the elements of turning by describing what a lathe is; and we then have chapters on tools, hardwood turning, metal-turning with hand-tools, slide-rest work in metal, the self-acting lathe, chuckmaking, turning articles of square section, screw-cutting by self-acting lathe, the overhead driving apparatus, choosing a lathe, grinding and setting tools, metal-spinning, Beddow's appliances, and ornamental drill and eccentric cutter. Then follow 68 pages of new matter, with 67 new engravings on the eccentric, the oval, and the dome chuck, the goniostat, the eccentric and the horizontal cutting frame, and a chapter on handy receipts and wrinkles. The work is one which is of much utility to those engaged in turning.

"Electric Transmission of Power."—Before leaving England, Mr. Kapp handed the final proofs of the fourth edition of his work on the "Electric Transmission of Power" to Messrs. Whittaker. The work has been brought up to date, both as regards theory and practice. Examples of the most recent installations of power transmission by continuous current, including the series arrangement of a number of machines for working at extra high pressure, have been added to or substituted for the examples in the third edition. The theory of continuous-current generators and motors has been further developed in accordance with latest investigations, and several new chapters have been added dealing with the transmission of power by simple and multiphase alternating current. The theory and construction of alternators, transformers, and alternating-current motors, has been added, as well as examples of large alternating-current plant successfully at work on the Continent. The book contains many illustrations and full particulars of dynamo-electric machinery made by the best English and foreign engineers.

Portable Accumulators.—A revised price-list of their manufactures has been issued by Messrs. Peto and Radford, of 57B, Hatton-garden, E.C. A noteworthy feature in the list is the variety of portable accumulators for different purposes. Among these may be cited the two-volt pocket accumulators which are suitable for cases where a compact and light battery is required for testing work, driving small motors, induction coils, etc. For stage purposes, the four-volt accumulators are used. These batteries can readily be carried in a belt placed round the waist, and which will accommodate four or five cells. This arrangement allows of a light being obtained for special use by employés engaged on work in magazines, gasometers, and the holds of vessels where a naked light would be dangerous. The portable accumulators are made in four standard sizes, having capacities ranging from six to twelve ampere-hours. A variety of portable lamps and carriage batteries next engages attention. Each set gives 12 hours' light, the increased number of volts giving a greater amount of light. Passing on from the table lamps, we note a low-resistance primary battery recommended for charging the accumulators, and a selection of electric jewellery for use with the pocket cells. Among other manufactures illustrated in the list may be mentioned protective dust and damp proof fittings for use in mills, factories, and chemical works; ammeters and voltmeters of the gravity and marine types, battery-cell testers, arc lamps and carbons, switchboards and switches, etc.

Electric Lighting in Germany.—The Saxon villages of Potschappel and Deuben have decided to construct a central station, the cost being divided equally between them. Since the Cologne Municipality have decided upon the electric lighting of the Hohestrasse, two arc lamps have been experimentally put up at two different places, which show a marked difference as compared with the gas lighting. The work has been carried out by Mr. Louis Welter, of Cologne. The Wilsdruff Municipality have decided to light the streets by means of 16 900-c.p. to 1,000-c.p. and four 400-c.p. arc lamps. Current will be obtained from the local private central station of Mr. Gustav Fischer. The Munich Gasworks have protested against the further extension of the electricity works. A site has been selected at Friederichroda for a central station. The project to connect Friederichroda with Gotha has fallen through. That the erection of a central electric light station in Dresden was much required is obvious from the large number of applications which are being made to the Municipality for light. Notification has been made that 15,000 lamps will be required for the Royal Palace and Court Theatre. The machinery for the installation will be supplied by the Helios Company, of Cologne. Three 800-h.p. steam dynamos will be put up at once. The system of mains will be carried out jointly by Messrs. Schuckert and Messrs. Kummer. The local authorities at Crefeld have decided to erect a municipal central electric station. As, however, the gas company has a monopoly for lighting until 1900, the current produced will until then only be used for working the trams and for electric motors for industrial purposes.

The Brockie-Pell Arc Lamp.—The Brockie-Pell arc lamp occupies a position which stamps it as one of the best lamps in existence, and the fact that over 7,000 are already in use demonstrates the great success that has attended it since its introduction some years ago. In this connection Messrs. Johnson and Phillips, of London and Charlton, who are the sole makers of the Brockie-Pell arc lamp, have just issued a revised price-list of arc lamps and accessories. This type of lamp is specially adapted for the illumination of streets. It has been largely adopted for this purpose—notably by the St. Pancras Vestry—by many corporations, including amongst the most recent those of Nottingham and Tunbridge Wells, and by the Ealing Local Board. Apart from this, the Brockie-Pell lamp is used by the English and Colonial Governments, and by those of Germany, Russia, Italy, and Japan. It has also been introduced in connection with the lighting of numerous public buildings, colleges, theatres, exhibitions, hotels, railways, docks, shipbuilding yards, etc. The double lamp will burn for 32 to 40 hours, and the cost of maintenance, owing to the simplicity of construction, is extremely low. It will work either with alternating or direct currents on 50-volt circuits, or two in series on 100-volt direct-current circuits, or three in series on 100-volt alternating-current circuits. The lamp is made in various sizes: for examining and photographing the interior of cannon a horizontal arc lamp is provided; whilst for optical lanterns the firm supply a small projector. Lamps for the illumination of mills and factories are also illustrated in the list, which concludes with reference to arc lamp accessories and views of the arc lamp carriers adopted by the Corporations of Wolverhampton and Blackpool. A leaflet enclosed in the list deals with a new short-series arc lamp of from three to fifteen amperes, and specially designed for use on low-potential circuits.

Electric Traction in Germany.—The municipal authorities of Leipsic have granted a 40 years' concession

Digitized by Google

for electric tramways in the town to the Allgemeine Elektricitäts-Gesellschaft, of Berlin. It is proposed to construct at first lines to the extent of about 15 miles, to which about 6½ miles will be subsequently added. The new lines will run alongside of the existing horse tramways, but will only use the latter's tracks at certain points. There will be 75 motor cars, each to carry 34 passengers, and about 50 trailers of the same capacity. The total estimated cost is £258,400. After considerable delays, at last it appears that the local authorities of Düsseldorf have come to an arrangement with Mr. von Tippelskirch for the construction of an electric tramway to Grafenberg. A scheme has been drawn up for an electric tramway between Hagen and Eckesey, accumulator traction being employed. This will be the first accumulator line in Germany. It is proposed subsequently to extend the line to Herdecke. On completion the Hagen street tramways will be turned into electric lines. The Allgemeine Elektricitäts-Gesellschaft propose to turn the horse and steam tramway, in which they hold a number of shares, and which runs between Daerlach, Carlsruhe, and Mühlburg, into an electric line. Good progress is being made in connection with the electric plant for the so-called "blue" circular tramway in Hamburg. The posts have been erected and the conductors are now being fixed. A number of the motor cars has already been completed by the works at the Falkenried railway station. It is expected that the line will be in operation by October. Negotiations are in progress between the Municipality of Eibenstock and Messrs. O. L. Kummer and Co., of Dresden-Niedersedlitz, for the construction of an electric tramway to the railway station. The electric tramway at Gmunden has been completed, and trial runs for the purpose of instructing the employés have taken place. The overhead trolley system is employed.

Cost of Producing Electrical Energy.—A paper on this subject was read recently by Mr. B. J. Arnold before the North-Western Electrical Association, St. Paul, Minn. After enumerating statistics dealing with continental and American practice, the author concluded as follows: I will briefly call attention to the approximate results we are now getting from the different portions of power stations, and what we ought to expect from future stations. First—boilers: a large number of stations running now are using boilers with plain furnaces, from which they secure an evaporation of 5lb. of water per pound of coal. By the introduction of water-tube or internally fired boilers or tubular boilers set in improved furnaces, we will secure an evaporation of 8lb. of water per pound of the same fuel. Second—engine and generators: while we now get an average commercial efficiency of 60 to 70 per cent. in direct-belted plants, and 50 to 60 per cent. in those using shafting, we can increase these efficiencies to 70 and 75 per cent. respectively by the adoption of fewer and larger direct-coupled units. This will not only reduce the cost of fuel and labour, but will decrease the amount of real estate required and make the total investment less. Third—while Europeans have recognised the advantage of the use of accumulators with batteries as auxiliaries in central-station work, we have been slow to see this advantage, but the tendency now among American engineers and central station men is to look with favour upon this adjunct, and as there are many cases wherein a battery plant as an auxiliary can be made to pay well, the probability is that we shall see in the next five years many such plants installed. With a properly-designed direct-connected plant we may reasonably expect to deliver a kilowatt-hour to the consumer in stations having a capacity of not over 1,500 kilowatts for five cents per kilowatt-hour, which includes total cost of production and depreciation on the plant, but excludes interest on the investment and profit, assuming that a good quality of bituminous coal can be had for 2dol. 50 cents per ton. In larger stations with cheaper fuel the cost can be brought to 3½ cents.

Testing of Insulated Wires.—Though the full report of the World's Fair judges on insulated electric wires is not yet in the hands of the Awards Commission, the awards have been made public. The judges in this department were Profs. D. C. Jackson, B. F. Thomas, R. B. Owens, and M. O'Dea, and the tests ordered by the Awards Commission were, according to the *Electrical World*, as follows: First, a breakdown test under high pressure to the point of rupture of the insulation, using a 2,000-volt Westinghouse alternating current. Second, a soak test extending over a period of sufficient length to exhaust all but the best wire, which proved to be 100 days, the test ending to April 1, 1894. There were five solutions used, as follows: (*a*) 10 per cent. sulphuric acid solution; (*b*) 10 per cent. ammonia solution; (*c*) a saturated lime-water solution with heavy sediment of lime; (*d*) a solution of subway refuse or scrapings from Chicago subways suspended in Chicago river water; (*e*) Chicago hydrant water. The wire used was No. 14 B. & S., with $\frac{3}{32}$in. insulation. There were 10 varieties of commercial wire subjected to this test; two samples 100ft. long of each were used and tested at least once a week for resistance and the figures kept for computing the final results. To these tests Prof. Jackson added a third, with the consent of the committee, which consisted of a combination breakdown and soak test. Five solutions made up as those in the second set of tests were used, the wires being connected up in short lengths to a 6,000-volt current and kept in circuit until the insulation was ruptured. Prof. Jackson and the other members of the committee are now preparing an exhaustive report on their work, but the results have been given out in advance along with awards to the successful competitors. The first award is to Mr. W. R. Brixey for "highest excellence in insulating qualities, durability of insulation under conditions found in commercial service, and uniform high excellence in mechanical qualities of insulation." Other awards were to the Okonite Company, New York Insulated Wire Company, Simplex Electric Company, Standard Underground Cable Company, and Norwich Insulated Wire Company. J. A. Roebling's Sons' Company received awards for bare copper and trolley wire, and the Washburn and Moen Company for bare copper wire.

The Government and Telephony.—Consequent upon the publication of the memorandum relating to the draft telephone agreements, which were abstracted in our last issue, questions on the subject were put in the House of Commons last week. Mr. A. C. Morton asked whether, having regard to the statement in the Treasury minute of May 23, 1892, upon the proposal for the development of the telephone system in the United Kingdom, that the intention was to meet, as far as possible, the views of the municipal authorities, and having regard to the fact that the proposals were embodied in certain draft agreements which had only just been circulated, the Postmaster-General would postpone until next session the completion of the agreements, so as to give the municipal authorities who had now adjourned an opportunity, which they would not otherwise have, of considering and expressing their views on the draft agreements. Sir A. Rollitt desired to know whether the public interest would not be likely to suffer from any further delay. Mr. Henniker Heaton asked the Postmaster-General whether he would consider the propriety of referring the Treasury minute to a committee of business men chosen from members of the House. In

Digitized by Google

reply, Mr. A. Morley stated that the committee which sat in 1892 recommended that the details of the arrangement should be carried out by the Department. He might perhaps be allowed to answer questions 43 and 47 at the same time. He had pointed out in reply to previous questions that the agreement did not require the confirmation of Parliament. He might again point out that it merely carried out the policy which had already received parliamentary sanction, and in connection with which large sums had already been expended out of the amount authorised to be raised by the Telegraph Act of 1892 in the erection of main trunk lines. As he had before stated, the telegraph estimates would afford an opportunity for any discussion that it might be desired to raise, and, in view of the inconvenience and prejudice of the public interests which the further delay desired by the members would involve, he was not prepared to assent to the postponement of the matter until next session. Not being content with this reply, Mr. A. C. Morton asked whether this agreement would not prevent the granting of any licenses to municipal authorities for a period of 18 years. Mr. A. Morley answered in the negative, and said that his discretion in the matter remained absolutely unfettered.

Driving Looms by Electric Motors.—The employment of electricity for lighting and power purposes has rapidly developed in the industrial district of Saint-Etienne, in the neighbourhood of which are not only large metallurgical establishments but also textile works, the products of which, especially in the case of ribbons, are known throughout the world. A noteworthy instance in connection with the latter industry is afforded by the factory of MM. Forest and Co., where 500 persons are employed. This building was reconstructed in 1891, and after having given the matter full consideration, MM. Forest and Co. came to the conclusion that electric power was preferable to the use of purely mechanical means for the operation of the looms and other machines in the works. Accordingly, MM. Vallot and Pauze, a local electrical firm, were entrusted with the work of installing the electrical plant. An illustrated description, from which the following particulars are abstracted, is given of the installation in *L'Electricien* of August 18. The plant comprises two MacNicol tubular boilers constructed by MM. Broyet, of Saint-Etienne, and which supply steam to a general heating system for the various rooms and for the operation of the steam-engine; and a horizontal condensing engine of 120 h.p. made by M. Piquet, of Lyons. This engine drives by belting two Sautter-Harlé dynamos giving 42,000 watts, the pressure being 70 volts at 600 revolutions. These machines are used partly for lighting and partly for power purposes. When the generators are at rest the offices and warehouses are lighted from a battery of 36 Tudor cells, supplied by M. Martin, of Saint-Etienne, and having a capacity of 200 ampere-hours. The battery is charged by one of the dynamos during the day. The illumination of the warehouses is effected by 50 six-ampere arc lamps, whilst the offices, etc., are lighted by means of 350 incandescent lamps. After having made some experiments, the Olivet-Dessaul type of electric motor was adopted for actuating the looms. There are 40 motors, which are arranged on the top of the looms, which drive them by means of belts and pulleys. When the loom is momentarily stopped, a loose pulley is brought into play which allows of the motor running free. The normal speed of the motors is between 800 and 900 revolutions, and when running without load it rises to 1,000 revolutions. The ribbon and velvet looms are operated by 60 motors, taking from 2·5 to 4 amperes at from 1,400 to 1,500 revolutions. In addition to these, there are seven motors installed of from 1 h.p. to 3 h.p., these being used for a variety of purposes. Simple switching arrangements are provided for cutting out the various motors when necessary.

Photographing the Effects of Telephone Vibrations. — A correspondent of the *Manchester Guardian* has written to that paper: "The problem has been attacked in a new way by Mr. G. J. Burch, who has succeeded in making an instrument by means of which the E.M.F. of the currents generated by speaking into a telephone can be recorded photographically. These currents are too rapid to affect an ordinary galvanometer individually, and inasmuch as they flow alternately in opposite directions their combined effect is nil. But it seems that the capillary electrometer, invented some years ago by Lippmann, has been brought to such perfection in Oxford that electrical changes occurring hundreds, and even thousands, of times in a second can be recorded by its means. The instrument consists of two glass tubes, one drawn out to a fine point, and the other bent into the shape of the letter V. The latter is about half filled with mercury, and contains in one limb a few drops of dilute sulphuric acid. Mercury is poured into the other tube, and is forced, partly by its weight, and partly by compressed air, into the narrow part of it, where it hangs balanced, as it were, by the force of capillarity. This tube is fixed so that its point dips into the acid in the V-tube. Platinum wires dipping into the mercury in either tube serve to connect the instrument with the circuit of the telephone. The smallest change in the electrical condition of the circuit instantly disturbs the balance of the capillary forces, and the end of the mercury column is driven up or down, according as the pressure of the current is towards it or away from it. These movements occur with a rapidity that the eye is unable to follow, and the instrument is perfectly dead-beat in its action—*i.e.*, there is nothing at all resembling the oscillations of the needle, which render observations with a sensitive galvanometer so serious. In order to record these movements recourse is had to photography. The magnified image of the capillary tube is projected on to a screen in which is a narrow slit. Behind the slit a sensitised plate is made to pass with a perfectly regular motion, any rise or fall of the mercury column being recorded as a projection or a notch on the edge of its shadow. This method was introduced by Prof. Burdon Sanderson. The apparatus now employed was invented by Mr. Burch. The first photograph shown was taken seven years ago. The electrometer was connected with a telephone, near which a whistle was blown. The currents generated were so intense as to cause electrolysis, and it was evident that the movements of the electrometer had been too rapid to be properly recorded on the photograph. This led to the construction of the present apparatus, in which the plate can be made to travel at any desired rate from 6in. to 6ft. per second. The next illustration was obtained by singing a falsetto note near the telephone, the electrometer having responded to the currents generated by each vibration to the number of 650 per second. From this result it was evident that the apparatus might be used for studying the sounds of the human voice in speech. The syllables 'pop-pop-pop-pop' and 'dod-od-od-od,' spoken during the passage of a plate, produced results easily distinguishable from each other and evidently characteristic of these consonants. The vowels 'a' and 'e' formed the subject of the next two photographs, and the last represented the buzzing sound of 'Z-z-z-z.' This gave a very irregular curve, and Mr. Burch stated that with the lens fine serrations could be distinguished which corresponded to from 2,500 to 3,000 double vibrations per second."

THE ELECTRIC LIGHT INSTALLATION AT ARUNDEL CASTLE.

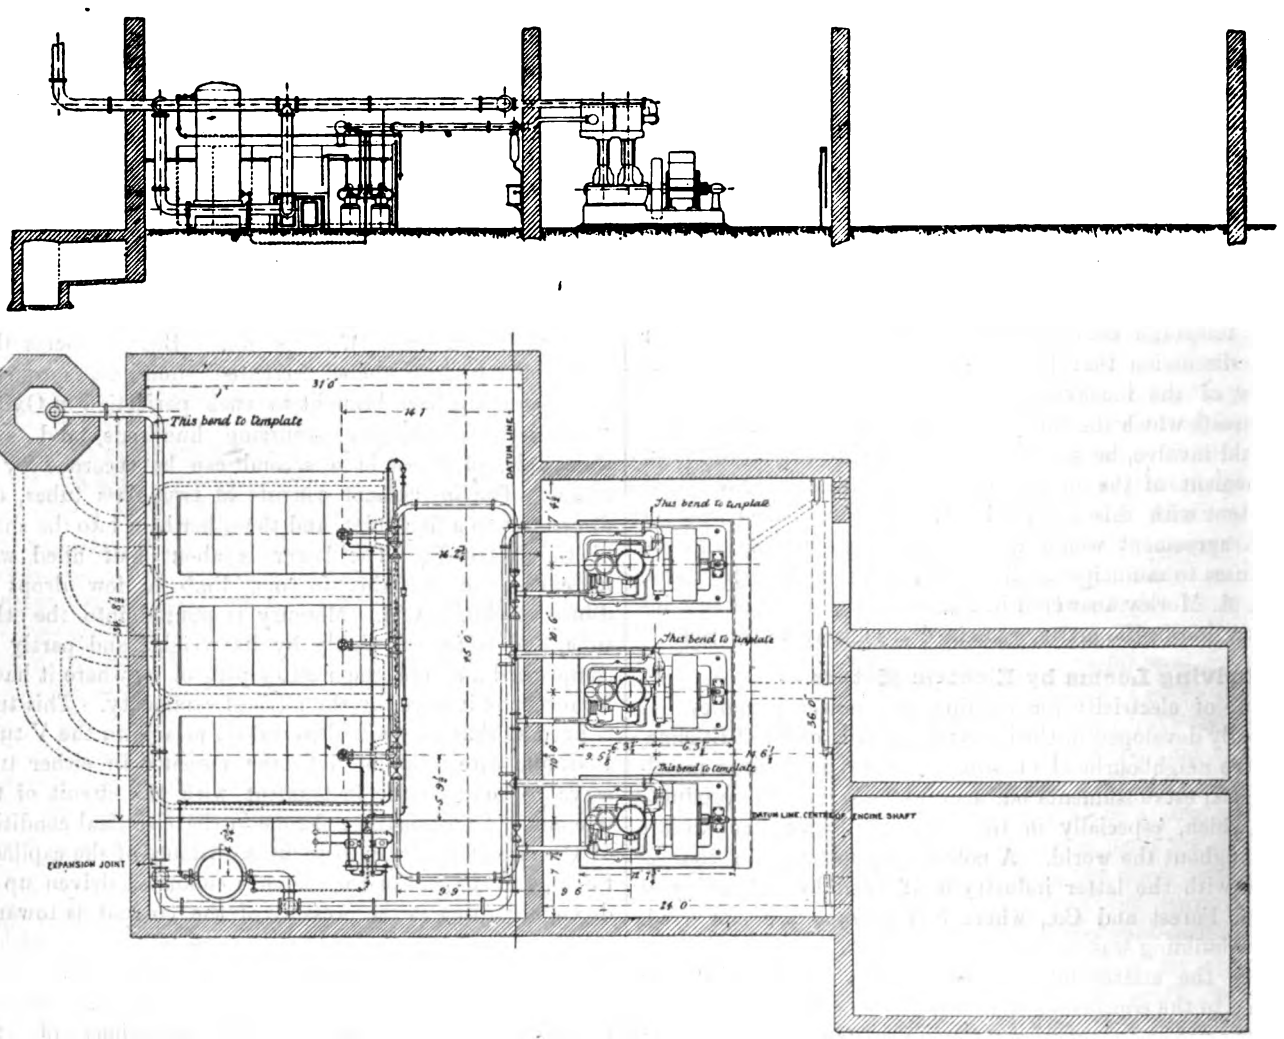

FIG. 1.—Arundel Castle Electric Light Installation—Plan and Section Showing the General Arrangement of Boilers, Engines, and Dynamos.

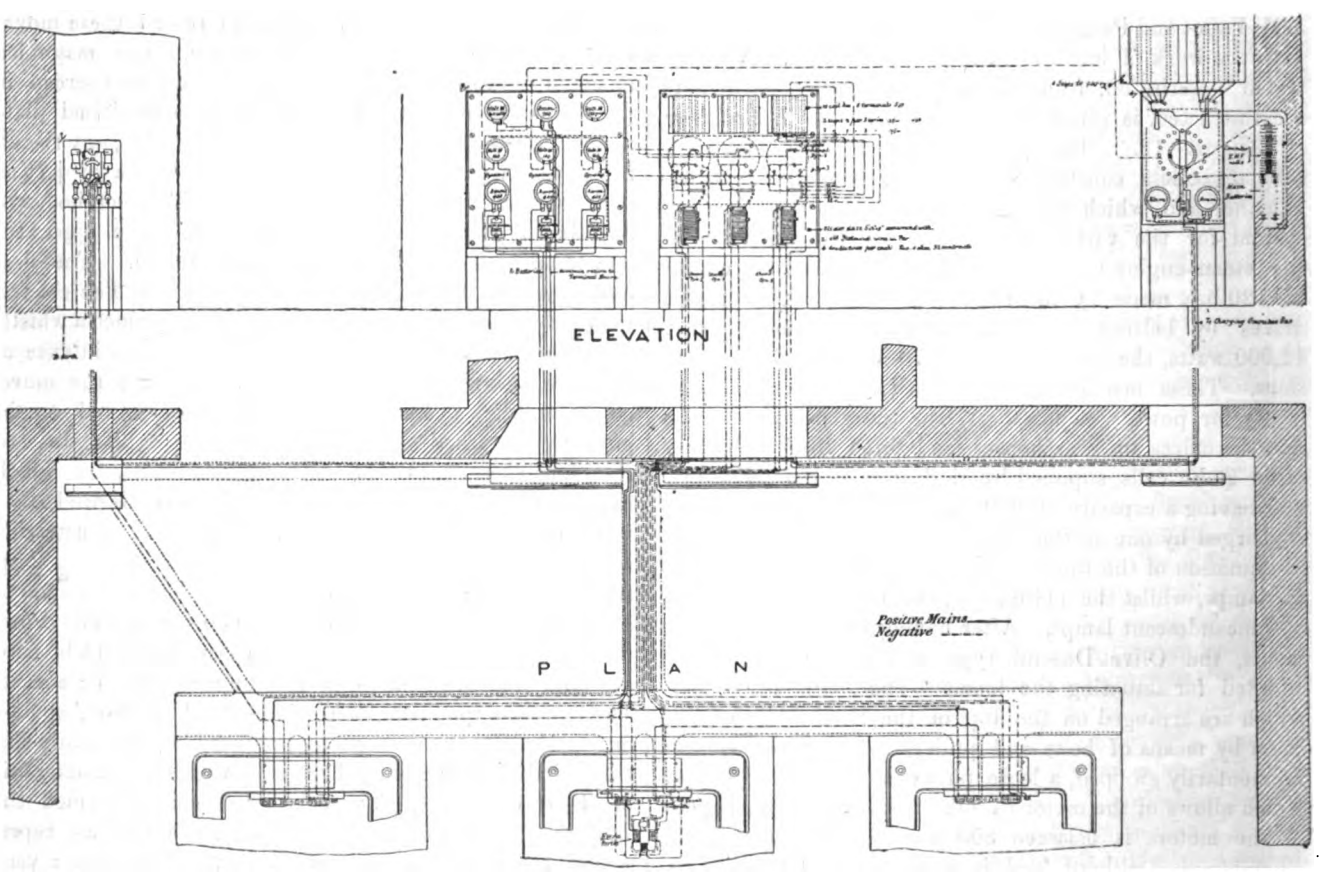

FIG. 2.—Arundel Castle Electric Light Installation—Arrangement of Switchboard Connections.

In our last issue we published plans and elevations of the buildings forming the generating station from which Arundel Castle and the grounds are electrically lighted. We now proceed to refer to the electrical features of the

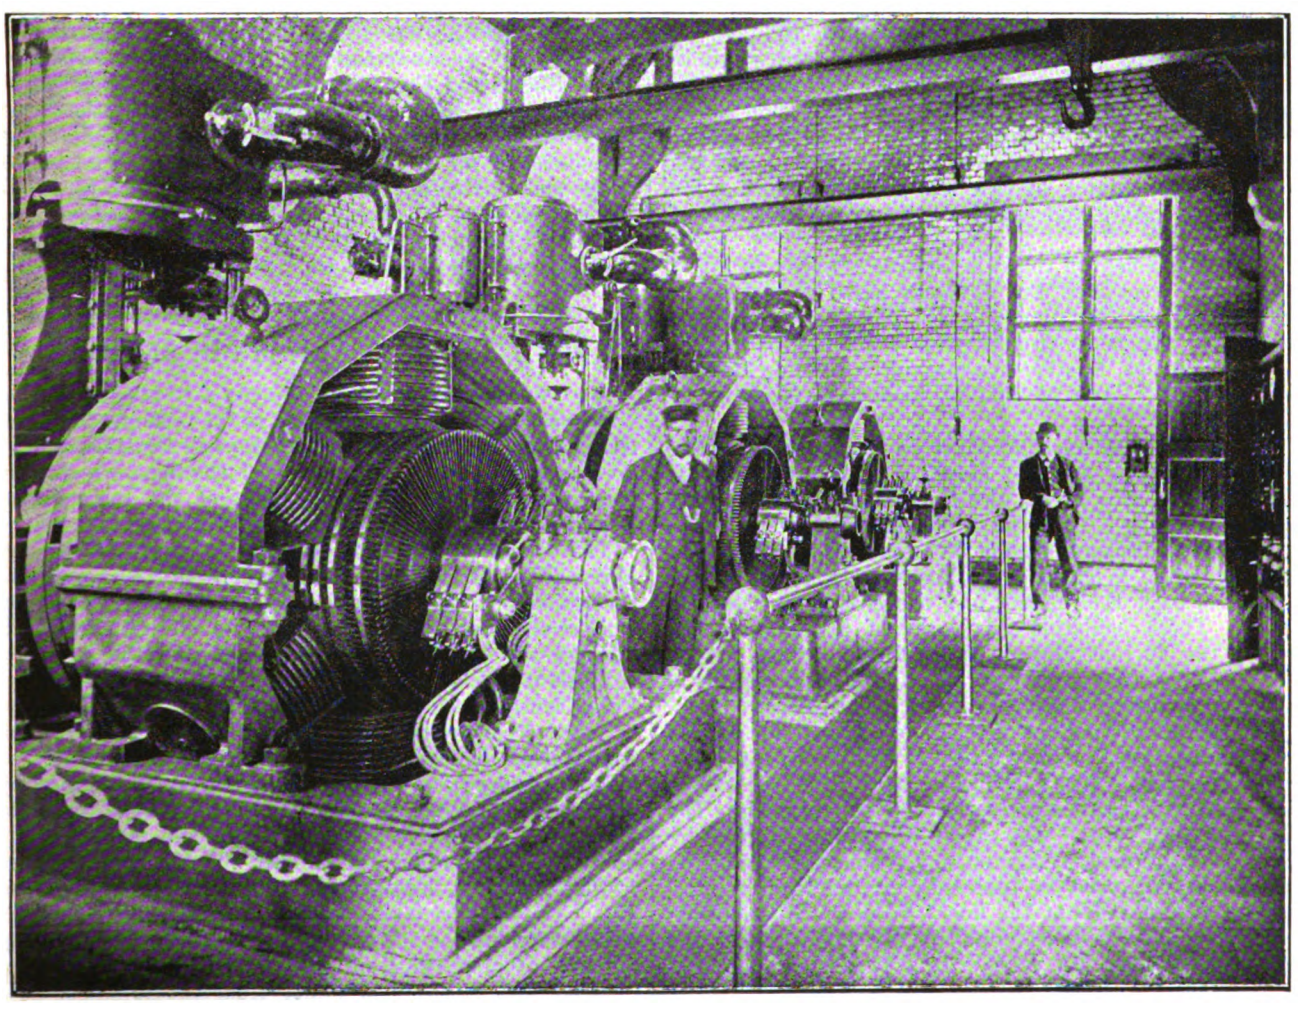

FIG. 4.—Arundel Castle Electric Light Installation—Internal View of Engine and Dynamo Room.

Digitized by Google

installation, illustrations of which are annexed. Fig. 1 is a plan showing the general arrangement of the plant; Fig. 2 is an elevation and plan showing the connections of the switchboards; Fig. 3 gives an internal view of the boiler-house, and Fig. 4 a similar view of the engine and dynamo room.

As mentioned in our last issue, the generating station has been erected in the new road at the top of Poorhouse-hill, near the entrance to the gardens. The building, which was commenced in 1893, is hidden from the road for much of its height by a wall. It has a total frontage of 92ft., with a depth of 48ft. and 36ft., and is divided into boiler-house, engine and dynamo room, accumulator-room, and fitting-shop. The boiler-house contains three Galloway boilers, 18ft. long by 6ft. 6in. diameter, and having two flues. Each boiler is capable of evaporating 3,300lb. of water per hour. There are two steam feed pumps, either of which is capable of supplying any two of the boilers, and one of Atkinson's feed-water heaters. The steam main is of wrought iron, and is arranged in a ring with valves, so that any boiler can work either engine. The exhaust main from the engines to the heater, and thence to chimney, passes round the boiler-house, and, as well as all other pipes, is neatly lagged.

The engine-room contains three 90-h.p. vertical inverted compound steam-engines of the Brush type, which are fitted with Raworth's expansion governor, adjustable by hand, whilst running at from 120 to 140 revolutions a minute. The engines are capable of indicating 140 h.p. To each engine is coupled direct a dynamo capable of working up to 400 amperes at from 128 to 160 volts. The engines and dynamos are mounted on a strong bed-plate on massive stone foundations.

The dynamos, which were made by Messrs. Johnson and Phillips, are of the multipolar type, each having eight poles. The armatures are drum wound, and are fitted with Kapp segmental connectors. Each machine is capable of working up to 64 kilowatts at a pressure of 160 volts when used as a simple shunt machine for charging accumulators at a speed of 155 revolutions per minute, and up to 51·2 kilowatts at 128 volts when used as a compound dynamo supplying lamps direct at the same speed. The compounding has been specially designed to give the required pressure at the castle voltmeter board within an error of two volts up or down between no load and full load. Each machine is mounted on an extension of the engine bed-plate, and is direct coupled to its own engine, running at the speed mentioned. The current is collected from the commutator by two sets of three brushes, 2in. wide, each having independent adjustment and hold-off catches.

The arrangement of the switchboards is shown in Fig. 2. As already mentioned, the dynamos have, in addition to the ordinary compounding, an extra compound winding in series with the main circuits, thus compensating for the loss in the mains, whether one machine is running alone or two in parallel. The method of connection is shown in the diagram.

The accumulator-room contains two sets of the H size D.P. accumulators, made by Messrs. Johnson and Phillips. There are 124 cells in all, and these in two parallels are capable of giving a discharge of 240 amperes for 3½ hours, and a normal discharge rate of 142 amperes for 10 hours. The regulation is effected by inserting a more or less number of back E.M.F. cells into the circuit, as shown in Fig. 2. These regulating cells consist of plain lead grids, and as the current always passes through them in one direction only, they are always well formed and capable of giving an opposing E.M.F. on the line when required.

The feeders passing out of the generating station are led to the distributing-room, which is situated in the old dungeon tower. They comprise two pairs of cables, each having a sectional area of ·80 square inch. The distance is 440 yards. The cables, which were supplied by Callender's Bitumen, Telegraph, and Waterproof Company, Limited, are arranged so that they can be readily interchanged at either end of the line. From this distributing-room a ring main is laid round the castle courtyard, the length being about 270 yards. It is connected at each of its extremities with the switchboards in the distributing room. This ring consists of a pair of cables having a section of ·80 square inch. The ring is tapped at four points, from which branches are run into the service switchboards placed in the corridors within the castle. A pilot wire is built up inside the main cable, and, in addition to this, a separate cable for indicating pressure, or for signalling, having three conductors each $^{7}/_{22}$, is laid from the generating station to the distributing-room, and connected thence to each of the castle switchboards. The main cable is formed of 60 wires each, No. 10 S.W.G., and is insulated by bitumenised fibre. This is sheathed by a heavy tube of lead, which is protected by thick servings of yarn dressed with preservative compound. The cables are laid direct in the ground under the turf and garden paths of the park, where they are quite free from all chance of injury. Half-way between the generating station and the distributing-room, boxes have been placed so that the mains can be disconnected for testing. Branch mains are also laid from the distributing-room to the lodge, and for supplying the lamps which will light the drive to the castle.

The current is led by insulated wires in the castle to the lamps in the usual way, with the necessary distributing switch and fuse boards. The conductors are all covered in neat wood casings, the positive and negative being distinguished from each other in black and red colours. There are separate switches to each room, and the principal rooms are arranged so that the whole, the half, or one-third of the lights may be used. A telephone connects the main switchboards at the generating station and the castle. The number of lamps at present arranged for the castle is 1,200. Only the east wing is completed and the lamps fixed. The wiring of the south wing is partially done, and is being proceeded with as the restoration of the castle is carried out. The courtyard and the drive from the lodge will both be lighted with incandescent lamps, from an independent main, by means of which the whole of the lights can be switched on or off, whilst a switch will also be provided for each lamp.

The buildings and the general arrangements of the plant have been carried out according to the designs of Mr. A. F. Phillips, C.E., of 31, Great George-street, Westminster, Mr. Gisbert Kapp acting as consulting electrical engineer. Mr. A. Bard, C.E., has acted as the resident engineer. The contractors for the buildings were Messrs. Reed, Blight, and Co. The whole of the machinery and electrical plant has been supplied and fixed by the Brush Electrical Engineering Company, Limited, under the superintendence of Mr. W. Geipel, M.I.E.E., who also laid the cables and carried out the wiring of the castle. Mr. J. E. Sayers has been in charge of the electrical section, and Mr. J. W. Donnet in charge of the mechanical department at the generating station.

THE ELECTRIC TRAMWAYS IN BRUSSELS.

A short time ago we referred to the opening to public traffic of two lines of electric tramways in Brussels, and we are now able to give a description of the lines, which were inspected last week by the members of the Incorporated Association of Municipal and County Engineers.

The whole of the work has been carried out by the Union Elektricitäts-Gesellschaft, of Berlin, who own the concessions for the Thomson-Houston patents. The lines worked electrically are those from the Nord to the Midi through the high circular boulevards, and the line from Brussels to Uccle.

The central station, which is situated in the Rue Broquier, at present comprises the following plant: three Babcock and Wilcox boilers, each having 235 square metres of heating surface; five compound tandem steam-engines by McIntosh and Seymour—diameter of high-pressure cylinder 13in., of low-pressure cylinder 19in., and stroke 15in.; number of revolutions per minute 235, working pressure 120lb., indicated horse-power 180, effective horse-power 150. The exhaust takes place in the atmosphere through a feed water heater. The feed water, which is previously purified, is obtained from a cistern of 90 cubic metres capacity, and is supplied either from the town mains or

Digitized by Google

from an artesian well. The steam-piping is in duplicate, so as to avoid any stoppage.

The five dynamos, which are driven direct by belt, are of the Brown tetrapolar type, with drum armature. These dynamos are each of 100 kilowatts (500 volts and 200 amperes normal output. The armature is toothed (Paccinotti type). The excitation is hyper-compound, regulated so as to allow for a loss of 10 per cent. pressure on the line. The switchboard has as many panels as there are dynamos. Each panel carries, in addition to the switches, an ampere-meter, a voltmeter, an exciting rheostat, a current indicator in the balancing wire, and an automatic cut-out, which isolates the dynamo when the current reaches a dangerous point.

The supply to the cars on the line is effected by two trolley wires of 8mm. diameter. This trolley wire is fed at intervals of about 500 metres by means of an underground feeder cable which is placed along the line. The section of this cable varies from 316mm. to 55mm. It is a Siemens cable having a copper core with two lead coverings and doubly steel armoured. It is placed in the ground on a bed of sand without any protection other than flat bricks, not mortared together, intended to indicate the position of the cable when the street is broken up. The trolley wire is divided into isolated sections, each of about 500 metres in length. Each section is connected at its two extremities with the feeder cable by means of cables inside the posts, the connecting cables carrying switches which allow of a section being put out of circuit in case of necessity. On the whole of the way along the boulevards the trolley wire is supported by iron arms fixed on hollow steel posts. In the streets the trolley wire is supported by cross wires of steel attached to the fronts of the houses. The wire is doubly insulated throughout.

The rolling-stock comprises 23 closed cars having 16 sitting places and 20 standing places. Each car has two motors of the W.P. type, each of 15 i.h.p. This power is sufficient to allow of hauling an open car carrying 36 passengers. The cars weigh 5½ tons empty and eight tons full. A motor car with trailing car weigh, loaded, about 13 tons. The average speed is 12 kilometres per hour, but owing to numerous stoppages the rate actually reaches at certain points 20 kilometres per hour. The cars are furnished with a series Carslett controller made by the General Electric Company, United States of America. This apparatus allows of the motors being at will put in series or in parallel, and of varying the intensity of the magnetic field so as to realise four degrees of normal speeds. The return is formed by the rails. For this purpose the rails, which weigh 30 kilogrammes per metre, are connected at each joint by two pieces of galvanised copper wire of 8mm. diameter. These wire are fixed to the rails by means of soft steel rivets. In addition, the four sets of rails are connected with each other at distances of about 90 metres. An experimental measurement of the resistance of the return gave a figure sensibly less than the estimated value of this resistance, although the earth connections are of little importance. This arises from the fact that other tramway lines connect the electric lines to the works, and all these lines tend to improve the conditions of the return.

The positive pole of the dynamos is connected with the trolley wires, the negative pole with the rails, and at the same time with two pits situated in the works. The telephonic protection consists of creosoted wooden arrangement placed above the wire. Protection against lightning is obtained by Thomson lightning arresters with magnetic blower. There are, of these arresters, one on each car, one on each section of the trolley wire, and one on each dynamo at the works. The following are the general particulars of the lines served: Boulevard line—length, 4,650 metres of double line being worked; maximum gradient, 6·2 per cent.; minimum curve, 20 metres. Uccle line—length, 3,925 metres; maximum gradient, 4·8 in 1,500 metres.

The switching apparatus on the car consists mainly of two drum commutators, which allow of any desired combination being effected. One of the drums serves simply to reverse the direction of the current in the two armatures for reversing the car. The second allows of the following combinations being obtained.

1. The two motors in series with all the resistance.
2. „ „ „ with a part of the resistance.
3. „ „ „ without resistance.
4. „ „ „ „ „ with a fraction of the field.
5. The same as the second.
6. One motor only with a part of the resistance.
7. The two motors in parallel with a part of the resistance.
8. „ „ „ without resistance.
9. „ „ „ „ „ with a part of the magnetic field only.

The driver is obliged to follow the above order in the various combinations. The combinations 3, 4, 8, and 9 are the only ones used in the course of running. The others are only transition combinations. An accessory apparatus allows of one or other motor at will being thrown out of circuit. A special appliance then prevents any combination beyond the fourth being made.

FACTS AND FIGURES CONCERNING SOME CONTINENTAL ELECTRIC TRAMWAYS.

(Concluded from page 145.)

With regard to the **Hamburg** electric lines, there arises no little interest from the fact that the entire tramway system in that city—amounting in all to nearly 156 kilometres (or 96·7 miles)—will be operated by electric traction within the next three years, in accordance with an agreement between the city authorities and tramway interests. At present, 126 kilometres (78·12 miles) are worked by horses, and seven kilometres (4·34 miles) by steam locomotives. There are 42 electric motor cars employed now, each with a carrying capacity of 30 persons. Of course, this number will be enormously increased when the whole of the lines are converted for electric traction. The average total daily distance run by the motor cars is 5,200 kilometres (3,224 miles). Their maximum speed is 16 kilometres (10 miles) per hour. The cost of current per car kilometre averages, as near as can be ascertained, 6 pfennig, equal to, say, 1·16d. per car mile. In the case of the steam locomotives, the *total* costs work out to 32·6 pfennig per car kilometre, or 6·3d. per car mile. These motors, however, also draw each a trail car, the total capacity of the two cars being 100 passengers. The horse cars will carry 24 persons, and are pulled each by a single horse; the total cost of traction being given as reaching 13 pfennig per car kilo metre, or 2·5d. per car mile.

Various technical descriptions have from time to time been published concerning the tramway at **Dresden**, and we do not therefore enter upon these features so much as its financial aspect and working conditions.

The following brief summary will serve to recall the chief constructional particulars: An overhead system is employed, with feeders; the current returns by the rails, return wires connected with the rails being also employed. Each motor car has two 8-h.p. motors, which drive the car axles through single-reduction gear. The switch lever for making and breaking circuit through the motors forms part of the brake handle, so that the two actions of starting the car and releasing the brakes—or *vice versâ*—are effected together. The line is four kilometres (2½ miles) long, and is almost entirely on the level, there being but one grade of 3⅓ per cent. The sharpest curve has a radius of 12 metres (say, 40ft., or two-thirds of a chain). In the central station are two sets of steam-engines, indicating 175 h.p. each; these drive a couple of Siemens dynamos, and are furnished with steam from water-tube boilers. The entire station is owned by the firm of engine-builders, Messrs. O. L. Kummer and Co., who supplied the steam plant, and undertake to provide the current required for the tramway at so much per unit or kilowatt-hour. There are nine motor cars, of which eight have longitudinal seats for 14 persons, with standing room for 14 more; the ninth car has transverse seats for 24 passengers, and accommodates 17 standing. With regard to minor points, as a result of working on this line, it is considered that the ordinary tramcars may be used for electric traction, if the underframes, and especially the end platforms, are suffi-

Digitized by Google

ciently strengthened by iron angle plates or other means. Iron underframes are, however, thought the best for motor cars, more particularly when the trucks are not of special design. Double-decked cars are approved of, so long as there is a roof or cover provided; in any such case, however, the overhead wire must be placed at least 18ft. above the street-level.

The capital outlay upon this line is as follows:

	Marks.		
Overhead wire system—four kilometres (2½ miles)	58,000	...	£2,900
Feeders, outgoing and return, two kilometres (1¼ miles)	17,000	...	850
Permanent way, etc., telephone connections, and sundries	152,000	...	7,600
Total	229,000	...	£11,450

	Marks.		
Cost per kilometre of line, with sidings	44,700	or per mile	£3,605
Cost of rails, paving, etc.	148,000		
or per metre of single line	31·49	or per yard	14s.
Cost of motor-car body, frame, etc.	3,000	.....	£150
Cost of electric equipment for motor car	5,900	.....	295
Total	8,900	.....	£445

The working results on this line are not considered to be very favourable, as it runs for the most part outside the chief lines of traffic in the city and surrounding districts. The annual traffic is at present only 250,000 car kilometres (say 155,000 car miles). The ordinary service is conducted at a pressure of 420 volts, with a current of 25 to 75 amperes, the maximum being 230 amperes at 500 volts. The average speed maintained is about 15 kilometres per hour (say 9·3 miles). A service varying from 7½ minutes to 15 minutes is given through the day; on Sundays, a number of trail cars are added. The mean daily travel is about 100 motor car kilometres (say 62 car miles). The maximum number of motor cars on the line which can be kept at work is 10, each drawing a trail car, and making 140 car kilometres (say 87 car miles) per day.

The annual cost of operating, based on results of one month (March), is as follows:

	Marks.		
Production of current in central station	23,214	or	£1,160
Wages, salaries, repairs, and materials	16,200	,,	810
Sinking fund	8,240	,,	412
	47,654		£2,382

This works out to ·188 mark per car kilometre, or, say, 4d. per car mile. Few accidents have occurred, and none of any importance. The following is the list: one suspension wire broken by derailment of trolley; a short-circuit between the outgoing and return feeders; and breakage of a stay wire owing to violent snowstorm.

Comparatively few details are available with respect to the line at **Essen**: this was equipped by the Allgemeine Elektricitäts-Gesellschaft of Berlin, and has a length of some 18 kilometres (11·16 miles). The steepest grade is 6¼ per cent., and the sharpest curve has a radius of 65ft., or, as near as may be, one chain. At one point of the system a curve of this radius coincides with a grade of 3·3 per cent. The central station has a total capacity of 400 h.p., half of which is sufficient to operate a service of 20 cars. The latter each have seating accommodation for 16 passengers, whilst 14 more can stand on the platforms. The trail cars are of similar size and capacity, and may be converted into motor cars if necessary, with slight alterations. As at Aix-la-Chapelle, the use of double-decked cars does not seem to be approved of. The cost of each motor car is stated to be 12,000 marks—say, £600.

The working pressure is 500 volts, and a current of 16 to 18 amperes is required per car in service. A speed of 12 kilometres (7½ miles) per hour is maintained; an average number of 16 cars is maintained on the road, travelling in all some 2,000 kilometres (1,240 miles) per day, or 77·5 miles per car per day.

At **Milan** a similar system is used, the line having been built and equipped by the Thomson-Houston Company. Its length is slightly over three kilometres—say, 1·8 miles—and wholly on the level; the sharpest curve on the line has a radius of not more than 48ft., or about two-thirds of a chain, though at the car-shed entrance there is one of 37ft. radius—say, half a chain. In the central station there are two dynamos of 100 kilowatts capacity, generating current at 500 volts. A compound condensing engine of 200 h.p. drives each machine; one set is usually kept in reserve, since the ordinary load is not more than 10 cars on the line, and six more might be operated. There are at present 13 cars in use or under construction; these each have sitting accommodation for 13 passengers, whilst 16 can stand on the two end platforms. The weight of each car complete with motor is about 5½ tons. With regard to the use of ordinary tramcars for electrical work, the management of the Milan line conclude that this is quite feasible so long as the trucks are properly altered. Double-decked cars are advantageous under certain conditions, but it seems better, as a general rule, to use the ordinary type with trail cars. The total cost of the line has been 446,674 lire, or, say, £17,867; of this the fixed plant is represented by 309,416 lire (£12,376), which is equivalent to 51,360 lire per kilometre (£3,313 per mile) of track, and 30,941 lire (£1,237) per motor car. The permanent way consists of Phœnix rails weighing 95lb. per yard. The rolling-stock has cost 137,257 lire (£5,490), or per car 13,725 lire (£549).

The working costs cannot fairly be ascertained or stated as yet, owing to the short period during which the line has been at work. The average number of cars on the line is 10, and the consumption of energy—based on the record of a wattmeter at the supply station—is about 5·7 e.h.p. per hour per car. The mean speed of the cars—including stops, both fixed and miscellaneous—is about 9 kilometres (5½ miles) an hour; their daily service averages 160 kilometres (say 100 miles) per car. So far the cost of traction has averaged ·276 lire per car kilometre (equal to 2¾d.), or, say, 4½d. per car mile, including cost of producing motive power, repairs to fixed plant and rolling-stock, wages and salaries.

At **Gera** there is an electric tramway line of metre gauge, having a total length of 11¾ kilometres, or 7¼ miles. The electric supply station serves not only to provide energy for this line, but also operates an electric lighting system in the town. The same plant and staff is used alternately as required for the tramway service, the charging of storage accumulators, and lighting direct. It is in consequence extremely difficult to separate out or properly apportion the expenses amongst the services thus rendered; and this can only be done with exactness after a few years have passed and enabled averages to be struck. So far as can now be ascertained, the cost of traction may be taken as 12·18 pfennig per car kilometre, each car having a capacity of 36 passengers. This is equivalent to nearly 2½d. per car mile, not including any allowance for sinking fund.

There are several lines now being operated in **Brussels**; the most important of them is perhaps that which connects the suburb of La Petite Espinette with La Place Rouppe in the city itself. This line has been erected on the Thomson-Houston overhead or trolley wire system by the Union Elektricitäts-Gesellschaft of Berlin. It has a length of nearly 13 kilometres (eight miles) in all, counted as single track, the actual distance traversed being 10½ kilometres, or 6½ miles. The shortest radius of curves may be taken at about 120ft., or, say, two chains: the greater part of the line, so far as gradients are concerned, lies on slight inclines up to 2·5 per cent., although for nearly one quarter of its length the grade reaches as much as 5 per cent. A curve of 1½ chain radius occurs at one point in conjunction with a grade of 5·3 per cent. At the central supply station are two condensing steam-engines each of 132 i.h.p., of which one serves to work the traffic, the other being in reserve. There are 12 motor cars on the line, each with a couple of 15-h.p. motors, and the same number of trail cars. The former have each seating accommodation for 24 passengers, and accommodate 11 persons on the end platforms. The trail cars are slightly longer, seating 20 only, but with standing capacity for 24. Double-decked cars are not used,

Digitized by Google

or thought advisable; they are looked upon as too draughty and cold, besides which it is considered that the getting on and off of passengers takes up too much time.

The capital outlay has so far been as follows:

Supply station buildings, chimney stack, water supply, etc.	£2,400
Electric generating plant, fixed	14,560
Motor and trail cars, 24 in number	12,960
	£29,920

or, in round figures, £30,000. This works out at £3,750 per mile of single track, or £1,250 per car. The cost of the latter has been £880 for each motor car, and £200 per trail car.

A second electric system at Brussels is operated by the Brussels Tramway Company, two lines—the Boulevards Circulaires Nord-Midi, and the Place Stéphanie to Uccle—being at present equipped. The former has a length of 4½ kilometres (say, 2·88 miles), and the latter nearly 4 kilometres (2·43 miles). The system employed is the Thomson-Houston overhead trolley wire method, with underground feeders. The greater proportion—at least two-thirds—of these two lines are built on grades ranging up to 2·5 per cent., but on the first line there is a length of nearly 300 yards on a 6·2 per cent. grade. The second line also runs for about half a mile on a 5 per cent. grade. The sharpest curves have radii of 80ft. to 100ft. In the supply station there is sufficient capacity for giving an output of 750 i.h.p. The rolling-stock comprises 23 motor cars each with seats for 16 passengers, and standing accommodation for 16 more. The average speed maintained on the first line is about 11 kilometres (6·8 miles) an hour, and 12 kilometres (7½ miles) on the second, including all stops.

THE BRITISH ASSOCIATION.

The following paper and abstracts conclude our *resumé* of the papers read before the British Association:

A Direct-Reading Form of Platinum Thermometer.

BY G. M. CLARK.

During the last few years much progress has been made in the subject of thermometry. This is more especially the case in instruments whose action is based on a change in electrical properties—such as the E.M.F. of a thermal junction, or the changes in resistance of a wire. It is to this latter class that the platinum thermometer belongs.

Whatever method of measuring temperature is adopted, the assumption may be made that the change measured is proportional to the changes in temperature. This assumption will give a scale of temperatures, depending, however, on the thermometric substance used, and which will not be the same when the thermometric substance is changed. In order to bring all such thermometric scales to a common basis, they have to be compared with the indications of the normal air thermometer.

In the case of a platinum thermometer we make the assumption that the change in resistance is proportional to temperature, and call the temperature so deduced the platinum temperature. Thus if R and R_o are the resistance in steam at 760mm. pressure and ice, $R - R_o / 100$ is the change in resistance per degree; and if R is the resistance at any other temperature the platinum temperature, $p\,t = (R - R_o) \div R - R_o / 100$.

The relation between the platinum temperature and the air thermometer scale has been experimentally shown to be expressed by the formula

$$a = t - p\,t - \left(\frac{t}{(100)^2} - \frac{t}{100}\right)$$

where t is the air thermometer temperature, and p is a coefficient whose value is approximately 1·50. This value of p varies slightly from 1·47 to 1·63 with different samples of wire, but its value can always be determined by observations at three different temperatures. Hence it is always possible to reduce the temperature as given by any specimen of wire either to the air scale or to that which would be given by some standard wire. This latter is the scale which one is almost forced to adopt when dealing with extremes of temperature. For, in the case of very low temperatures—*e.g.*, where air liquefies—the air thermometer is obviously no longer serviceable, and at very high temperatures, above 700deg. C., reliable experiments with the air thermometer have yet to be carried out.

The departure of the platinum scale from the air scale is not greater than the departure of the mercury scale from the air, so that those who are accustomed to accept mercury thermometer readings without hesitation will not have the order of accuracy of the observations reduced by accepting the platinum scale. In the construction of a direct-reading instrument it is obviously advantageous to have a scale divided into equal parts. The platinum scale has therefore been adopted in the direct-reading thermometer of Callendar and Griffiths. This instrument is most easily described in two parts—(1) the thermometer itself, (2) the indicator.

In the thermometers, the platinum wire of ·008 in diameter is wound non-inductively on a wire formed about 2in. in length and ⅜in. in diameter. In order to eliminate changes in resistance in the connecting leads, the stem of the thermometer contains four leads insulated by means of washers. Two of these are connected to the ends of the coil; the other pair, called compensators, are joined to fetters just above the coil. The lower 12in. of these leads are of thick platinum wire; these and the coil are protected by a glazed porcelain tube. The choice of a suitable material on which to wind the coil and the complete protection of the wire from furnace gases, are both points of considerable importance. Neglect of these precautions in the earlier forms of hygrometers fully accounts for the changes which they used to undergo. The upper portion of the leads are of copper, fixed to the platinum, and insulated by being threaded through pipe stem. They are protected externally by a steel tube, which may be extended to protect the porcelain tube in cases where the thermometer is liable to rough usage. The upper ends of the copper leads terminate in four binding screws, to which the leads connecting thermometer to the indicator are attached. These connecting leads may be of any length, so long as their resistance is not much greater than ·5 ohm. The indications of the thermometer can then be read at a distance from the place under observation.

The resistance of the platinum coil is adjusted so that the change in resistance for 100deg. C., from ice to steam, is one ohm, or, in other words, each degree is equivalent to an increase in resistance of ·01 ohm. The platinum coil has therefore a resistance of ·258 ohms at 0deg. C.

The measurements of resistance or temperature are made in the eudicator, which consists essentially of a Wheatstone's bridge of a specially-arranged galvanometer.

The two ratio arms of the bridge are made equal, and have a resistance of about 20 ohms. In the third arm of the bridge are 15 resistance coils, each of one ohm, and the thermometer is introduced in series with these. The fourth arm is made up of the compensating leads and a coil whose resistance is such that the whole bridge is balanced when the thermometer is at 0deg. C. The battery used consists of dry cells giving about two volts at the terminals of the bridge, so that the current through the bridge is about one-tenth of an ampere.

In the galvanometer the moving portion consists of a combination of steel magnets pivoted on a needle point, and to these a light aluminium needle is attached swinging in a horizontal plane. The movement of the system is controlled by two sets of coils. These are arranged so that one pair is parallel to the pointer at the zero position of the scale, the other pair at right angles. The former pair are the equivalent of the ordinary galvanometer coils, the latter are in the direct battery circuit. Since the resistance of each arm of the bridge remains practically constant, the current which passes through the galvanometer coils will always be the same proportion to the current in the battery circuit whatever the E.M.F. of the battery may be. The deflections of the galvanometer are, therefore, independent of the strength of the battery. The adjustment of the strength of the two sets of coils is made by means of a low resistance across the field coils in the battery circuit. This is adjusted until the galvanometer swings across the scale for an increase of one ohm in the thermometer arm. The scale is divided into 50 parts, each representing $\frac{1}{50}$ of an ohm, or 2deg. As each of these divisions are about $\frac{1}{25}$ of an inch the scale can easily be read to 1deg. For greater convenience the scale is repeated on the other side of the zero, so that the whole range of the scale without altering the resistance coils is 200deg.

The resistance coils are all made of manganised wire, annealed and protected from air. There is thus no connection to be introduced for changes in temperature of the air. The instrument is also unaffected by changes in temperature of the leads to the platinum coil, for since these are in duplicate and are placed in opposite arms of the bridge, any temperature change in one pair will be balanced by the same change in the other pair. The balance of the bridge is thus only affected by the temperature changes in the coil itself. When the platinum coil has been heated through 100deg. it will have increased in resistance by one ohm, and the galvanometer pointer will be deflected across the scale. The resistance of this arm of the bridge can now be made the same as before by plugging in the one-ohm coil, and the galvanometer returns to zero. The scale is then repeated every 100deg., and thus a wide range of temperature and an open scale are obtained at the same time. The temperature is then directly read off—the hundreds of degrees by the coils plugged in, and the remainder on the scale.

Digitized by Google

A further advantage of this arrangement is that any error in the original adjustment of the swing, or want of permanence in the system, does not produce any cumulative error. A truly graduated scale would not be one of equal parts, though it is not, as might appear at first sight, a tangent scale. The error introduced by the equal scale, however, is small, and the above remark about its non-cumulative effect applies to it also.

A very common objection to this form of hygrometer is the statement that its fixed points change after exposure to high temperatures. The only answer I can give to his objection is that in the experiences of those who have experimented with this form of hygrometer, its most distinguishing feature is the permanence of its fixed points. The objection is only urged by those who have no experience of the instrument, but is based on the report to the British Association in 1874 appointed to examine one particular form of instrument only. As an illustration of the permanence of the fixed points I may give the following: One of these instruments was immersed in melted silver, the source of heat being an oxyhydrogen flame playing on the bottom of the crucible. This crucible by some means became broken, the silver poured out, and the oxyhydrogen flame was left playing directly on the lower end of the porcelain tube for some time before the accident was discovered. As a consequence the lower end of the tube became fused. On subsequent examination it was found that the wire coil and leads had become embedded in the porcelain, and it was impossible to remove the interior of the instrument. On trial in ice, however, the freezing point was found unaltered.

The porcelain tube may thus be considered as completely satisfactory in protecting the platinum coil. The difficulty of the protection of the stem is one which has not as yet been fully overcome. The difficulty is not insurmountable, as it might be met by extending the porcelain tube the whole length of the stem. Such tubes are, however, difficult to obtain, and if broken would be expensive to replace.

The second objection is the adoption of a new scale of temperature. As bearing on this point I may quote from Callendar's paper on "The Practical Measurement of Temperature in 1886": "We at present require a practical standard to which all measurements may be directly referred; the question of its exact relation to the absolute thermodynamic scale may be matter for subsequent investigation, and can best be solved when we have arrived a more accurate and extended knowledge of the phenomena of heat, of the dependencies of radiations, conductions, etc., on temperature measured in a scale, which may be to some extent arbitrary, but which will have the incalculable advantage of uniformity so that the results of different experimentalists will be accurately comparable."

It must be borne in mind that if circumstances render it advisable to express the temperature on the air scale, the relation as given by the D formula has been established up to 700deg. C., and that there are indications that it holds over a far more extended range. One fact will, I think, show the accuracy of the above formula, which was determined by Callendar in his exhaustive comparison with the air thermometer in 1885. In 1890 Griffiths came to the conclusion that the relation apparently established by Callendar was in error at temperatures above 450deg. C. In assuming Regnault's value for boiling point of sulphur, 448·3, the difference between this and air temperature from the platinum temperature, as deduced by Callendar's formula, was found to be about 5deg. It was evident that either Callendar's or Regnault's conclusions were incorrect. A redetermination of this boiling point of sulphur by direct measurement with the air thermometer was made in 1891, when it was found that the true boiling point of sulphur under a press of 700 m.m. was 444·5—a result in almost exact accordance with the temperature obtained by using platinum thermometers and the assumption of Callendar's formula. It is difficult to imagine a more conclusive proof.

Evidence that this relation between the platinum and air scales also holds at very low temperature are not wanting. In a communication to the *Philosophical Magazine* by Griffiths and myself in 1892, we pointed out that if we assume that R becomes 0, and also assume that the D formula holds over such a range, the result in temperature is in the immediate neighbourhood of −270deg. C. According to the experiments of Profs. Dewar and Fleming, it is at this temperature that the resistance of pure platinum should vanish.

Although there is so much evidence that the D formula is correct throughout the whole range of the platinum thermometer, still it is never safe to extrapolate beyond the range of actual experiment. I would, therefore, suggest that all measurement of temperature be referred to a standard platinum thermometer in which $p = 1{\cdot}50$. There is no necessity that such a thermometer should actually exist, as it is only a matter of calculation to reduce the observed platinum temperature to the standard.

Address to the Geological Section.

The president, L. Fletcher, M.A., F.R.S., F.G.S., in the course of his presidential address, which dealt mainly with crystallographical questions, after referring to systems of crystallisation, crystallographic notation, and similar questions, touched upon electrical properties in connection with crystals in the following paragraphs:

Piezo-electricity.—The most remarkable addition to our knowledge of the relation of minerals and electricity has been the recent discovery of the electrification produced by strain (piezo-electricity). It has been shown by J. and P. Curie that if a quartz plate, with faces cut parallel to the axis and silvered to make them conductive, be strained in a certain direction, the two faces either become oppositely electrified or show no signs of electrification at all, according as the faces of the plate are cut to be perpendicular to the prism faces, or to pass through the prism edges. Lord Kelvin says that this result is explicable by electric eolotropy of the molecule and by nothing else, a character which he had suggested for the molecule 34 years ago: experiments confirmatory of this hypothesis of the permanent electrification of the molecule were made some time ago by Riecke.

Pyro-electricity.—The development of opposite electricities at different parts of a crystal during changing temperature (pyro-electricity) has long been known in the case of tourmaline. We owe to Hankel a long series of investigations of this kind relative to boracite, topaz, and various other minerals, but it seems to be now established that most of the electrifications observed by means of his method are really piezo-electric, and are due to strains caused by inequality of temperature in different parts of the cooling crystal. A model has been lately made by Lord Kelvin which gives a perfect mechanical representation of the elasticity, the piezo-electricity, and also the pyro-electricity of a crystal.

Electrical Methods.—A delightfully simple method of investigating the difference of electrical condition of the parts of a cooling crystal and of making the distribution of electricity visible to the eye has been invented by Kundt. Mixed particles of (red) minium and (yellow) sulphur are oppositely electrified by their passage through the meshes of a small sieve; falling on the cooling crystal, each particle adheres to the oppositely electrified region, and the electrical condition of the latter is thus immediately indicated by the colour of the adherent powder. Mr. Miers remarks that this method is practically useful as a means of discrimination even when the crystals are extremely minute.

Hertzian Waves.

BY PROF. OLIVER LODGE.

The author described some experiments to illustrate Clerk Maxwell's theory of light. He began by saying that his experiments referred to the waves generally known as Hertzian waves, though Maxwellian waves would be a more correct term. Various detectors of electric radiations were now known, but the most sensitive was one which depended on the breaking down of the resistance of a bad electrical contact when electric surgings passed across it. Such a bad contact could be made by a row of iron borings in a tube, or by a steel spring with its end resting on a metal plate. These instruments he called "coherers," from the fact that when exposed to electrical waves their resistance was diminished, the particles cohering together, as it were, so that when connected with a battery and galvanometer the latter showed an increased current. The original resistance could be restored on tapping. Using for radiator a sphere charged from an induction coil, he exhibited the phenomena of reflection, refraction, and polarisation of electric waves of about 9in. in length. The coherer could detect the surgings in a sphere 5ft. away when charged by an electrophorus, or the oscillations in an electric gas-lighter; in Liverpool a sphere nearly 70 yards distant had affected the instrument. Polarisation was shown by gratings of parallel wires which stopped vibrations along the length of the wires and allowed those perpendicular to the length of the wires to pass undisturbed. One interesting experiment consisted in resolving a polarised beam into two beams polarised at right angles (elliptic polarisation) by one of these gratings. Reflection from gilt paper and from a block of wood at the polarising angle were also exhibited. It was also shown that glass was transparent to these waves. The phenomenon of refraction was seen by the bending of a wave out of its course by means of a large prism of paraffin wax, but a lens intended to concentrate the rays to a focus was not so successful, although Dr. Lodge said the experiment had often succeeded in his own laboratory, and its failure was due only to the disadvantageous conditions under which he had to work. He subsequently showed that the coherer would not respond to long waves like those produced by the discharge of a Leyden jar, and that the change in its resistance was effected whether a current was passing through it at the time or not. Prof. Lodge then described an electrical theory of vision. He said the rod and cones of the eye were of such a diameter that light falling on them would excite transverse vibrations in them. It had occurred to him that such

Digitized by Google

vibrations might increase the resistance of some part of the eye—perhaps the pigment cells—and thus the light stimulus would be recorded. Another stimulus would be necessary to correspond to the process of tapping which restores the coherer to its original state; this would be the sensation of darkness, and would be an actual positive sensation, not a mere absence of light. Between the stimulus of light and that of darkness there would be persistence of vision. Dr. Lodge showed an experiment to illustrate this, the coherer being restored by periodic tapping applied by a clockwork arrangement. For a continuous radiation the coherer showed continuous indications, which died away when the radiation ceased.

Discharge of High-Pressure Electricity through Gases.

Prof. J. J. Thomson, F.R.S., Cambridge, showed experiments illustrating the phenomena that accompany discharges of high-tension electricity through gases, and the conditions by which the discharges are influenced. In moist gases discharge as a rule starts easily and immediately, but when the gases are dry the discharge takes place either with great difficulty or not at all. If, however, a brush discharge is caused to pass through the gas the ordinary discharge begins and continues. It is in the starting of the discharge that the presence of moisture has the greatest influence. If the tension of the electricity is sufficiently high, the discharge will take place in gases as dry as it is now possible to get them. It seems probable, however, that if the gases could be made perfectly dry, no discharge would take place with any tension, however high. In some cases, and notably with oxygen and cyanogen, after the discharge has been cut off the gas remains luminous for a considerable time. This phosphorescence is due to the gas itself, and not to the vessel which contains it, and it is not observed when the oxygen and cyanogen are quite dry. With air, however, the phosphorescence is not observed when moisture is present, but appears if the gas is dry. The potential difference required to separate the atoms of gases from one another is extremely high, and it would seem that this separation requires the preliminary formation of aggregates of molecules that afterwards help by their relative instability to pull one another asunder. It is well known that in an electric field water vapour tends to collect in small drops, and these drops may form nuclei round which these aggregates can form. It is probable that the high specific inductive capacity of water may be an important factor. Temperature affects the electric discharge through gases in much the same way as it affects chemical changes. The facts that electric discharges through gases and chemical changes are affected in much the same way by the presence or absence of moisture, by temperature, and other conditions, seem to show that there is an intimate connection between electric discharges and chemical changes, the latter being conditioned by the electrical charges of the reacting atoms and facility with which these charges can neutralise one another.

NOTES ON ELECTRIC POWER, WITH SPECIAL REFERENCE TO WORKS DRIVEN BY ELECTRICITY IN BELGIUM.*

BY D. SELBY-BIGGE.

Last May the author of these few notes had the honour of submitting to the Iron and Steel Institute a paper on "Electricity as a Motive Power in the Iron and Steel Industries,"† in which he treated the subject somewhat closely, and at considerable length. The author has often thought that in countries where no very large water powers exist, such as the powers available in our counties of Lancashire and Yorkshire, turbine dynamos might be laid down at the different falls, and the power distributed to one collective centre, where the greatest demand for current would arise; in this way, many falls which, though formerly employed in the driving of factories, have been abandoned owing to their distance from main lines and high railway dues, would again be brought into use. There are, however, many, if not the majority of countries, in which water powers are few and far between, and the next best means for the economical driving of works has to be considered. The author has already pointed out and laid great stress upon the utilisation of waste furnace gases for producing steam in the boilers connected with the electric generating plant; in those cases where such a course is feasible, the cost of production per unit of electrical energy must necessarily be very low, and in order to arrive at a figure, it would be necessary to put a fixed value upon the quantity of waste gases used for firing the boilers, providing steam for running the electric generators at a fixed load, and for a given time. The cost of wages, oil, waste, upkeep, and incidentals could be arrived at in the ordinary manner.

The question of cost of production of electricity to be employed in driving engineering works, steelworks, shipyards, and factories of any description, must necessarily be of the first importance when considering an application of electric power; and in order to convey an accurate idea of the probable cost, the author will refer to some of the Board of Trade returns of electric lighting stations in England for 1893, showing what has been the cost of production to different companies.

Name of company.	Total h.p. capacity of engines.	Cost of production and distribution per unit delivered to consumers.				
		Coal.	Oil, waste, water, engine-room stores, and carbons.	Salaries of engineers and wages.	Repairs and maintenance.	Total.
			Low tension			
		d.	d.	d.	d.	d.
Liverpool	3,800	0·93	0·16	0·38	0·64	2·11
Westminster.....	4,530	0·78	0·19	0·95	0·35	2·27
			High tension			
Newcastle District.	1,200	0·83	0 28	0·85	0·14	2·10
Newcastle Supply.	1,200	0 63	0·18	0·77	0·53	2·11

It is hardly correct to compare an electric power station with an electric lighting station, but it may be taken that in power work where it is possible to use larger generators than is usually advisable in electric lighting stations, the cost of production should be rather less than more, and when waste furnace gases are available the cost of production should certainly not exceed one penny per unit of 1,000 watt-hours. The author's experience would lead him to suggest that for large-sized power generating dynamos of 300 h.p., 500 h.p., 800 h.p., and 1,000 h.p., an efficiency of between 90 per cent. and 92 per cent. may be expected.

In the case of motors, the following:

For	3	h.p.	motors an efficiency of	78	per cent.
,,	5	,,	,,	80	,,
,,	8	,,	,,	84	,,
,,	11	,,	,,	86	,,
,,	16	,,	,,	87	,,
,,	20	,,	,,	87	,,
,,	40	,,	,,	89	,,

As to the loss in transmission through heating of cables, leakage, etc., this should not exceed 3 per cent. in cases where the motors are situated at distances from the generating source of not more than 300 yards, and 5 or 6 per cent. in cases where the distance does not exceed 500 yards; this, however, cannot be taken as a hard-and-fast rule for every case, but it will be found to apply in the case of most works, and the expenditure of copper in the mains will not be found to be prohibitive.

The contention of the author in advocating electricity as the right and proper agent for operating new works, and as a means whereby old works can be remodelled, may be summarised by the one word "economy." In no country, perhaps, have engineers looked more thoroughly and closely into the economics of electricity as applied to power work than in Belgium, and the author trusts that reference by him to works driven by electricity in this country may not be out of place at the present meeting. In the first instance he would refer to an installation which has now been at work for some considerable time—viz., that of the National Arms Factory, at Herstal, near Liège.

Mr. Leon Castermans, in a communication which was published in the *Revue Universelle des Mines*, stated that towards the end of 1886 the principal arms manufacturers at Liège formed a syndicate with the intention of laying down works to carry out in a rapid manner important orders for guns. A company was eventually formed, under the title of the Fabrique Nationale d'Armes de Guerre, and an order was given to this company for 150,000 to 200,000 rifles. In order to carry out this work, the society determined to lay down works provided with all the latest improvements, and up to date in every respect. The Compagnie Internationale d'Électricité went most closely into the matter, with the result that they were able to offer to the syndicate absolute guarantees for successful working which have since been fully realised. When these works were started, the Compagnie Internationale d'Electricité laid down:

Nine motors of	16	h.p.	=	144 h.p.
Two ,,	21	,,	=	42 ,,
Two ,,	37	,,	=	74 ,,
Total.....				260

For each motor the Compagnie Internationale d'Electricité guaranteed: for the 16 h.p., a commercial efficiency of 87 per cent.; for the 21 h.p., a commercial efficiency of 87 per cent.;

* Abstract of paper presented to the Brussels meeting of the Iron and Steel Institute.

† *Vide Electrical Engineer*, May 11, 1894.

Digitized by Google

for the 37 h.p., a commercial efficiency of 89 per cent.; so that the available power would be produced by an initial power of—

$$\frac{144}{0{\cdot}87} = 165{\cdot}5$$

$$\frac{42}{0{\cdot}87} = 8{\cdot}34$$

$$\frac{74}{0{\cdot}89} = 83{\cdot}1$$

Total ..... 296·9 h.p.

As the loss by canalisation would not be greater than 2 per cent. :

$$\frac{296{\cdot}9}{0{\cdot}98} = 303 \text{ h.p.}$$

at the dynamo terminals.

In addition to the above there was a large amount of lighting to be considered, and the power eventually adopted was an engine and dynamo combined of 500 h.p. This dynamo is of the shunt-wound type, and suitable for a tension of 125 volts ; there are 20 pole-pieces formed in the form of a circle round the armature, and allowing a play of 6mm. to the latter. The armature, on account of its large dimensions, some 17ft., had to be built up *in situ*. The current is taken from two commutators, one on either side of the armature, by 80 metallic brushes ; the current is taken away to the main distributing switchboard by four underground cables. The commercial efficiency—that is to say, the ratio between the electric energy available and the energy transmitted to the shaft by the engine—was guaranteed to be 90 per cent. The carcase, which is in steel, of the dynamo weighs 10 tons ; the armature alone weighs 10 tons ; the copper in the magnets weighs two tons ; and the armature coils 600 kilos. The particular characteristic of this dynamo is that not only it is driven direct by the steam-engine, but that the armature itself forms the flywheel of the engine.

The motors about the works drive different line shafts. The efficiency of transmission—that is to say, the ratio between the power available and the effective horse-power developed by the steam-engine—is given by the product of the three efficiencies:

98 per cent. guaranteed for the dynamo ;
98 per cent. guaranteed for the conductors ;
87 per cent. guaranteed for the motors ;
=76·6 per cent.

The installation at Herstal has now been running continuously for three years, and until recently the entire works depended solely on the running of this single dynamo, both for light and power. About 2,000 hands are employed at the works. Up to the present, the large dynamo has never been the cause of the cessation from work for a single minute. The installation has of late been considerably extended, and an additional 300-h.p. plant has been laid down. The speed of the large engine and dynamo is only 66 revolutions per minute. The engine employed, being of the Corliss compound condensing type, was built by Messrs. Van de Kerkchove, while the dynamo was constructed by the Compagnie Internationale d'Electricité, under the direction of Mr. H. Pieper. The 300-h.p. plant consists of a combined Willans engine and Pieper dynamo, running at about 350 revolutions per minute, and it is interesting to compare the results obtained with these two engines. The efficiency of the Corliss combined plant—that is to say, the efficiency of the engine and dynamo taken together under full load, is about 77 per cent.

The dry steam consumption of the engine per indicated horse-power per hour=14·34lb.

The dry steam consumption of the engine per electrical horse-power per hour=18·75.

On the other hand, we get the highest efficiency from the quick-running plant. The efficiency of the Willans engine and dynamo combined at full load is about 85 per cent.

Dry steam consumption per indicated horse-power per hour=15·4lb.

Dry steam consumption per electrical horse-power per hour=18·19lb.

At the zincworks of the Vieille Montagne Company, near Jemeppe, a large electric power installation has recently been laid down. The works were formerly driven by a large number of steam-engines, which took from 60lb. to 88lb. of steam per indicated horse-power per hour to drive them, and required a number of enginemen to attend to them. The station is placed alongside the railway, so that coal may be brought right up to the boiler-house by truck. Three Babcock and Wilcox boilers have been laid down—one acting as spare, while the other two provide steam for a 600-h.p. compound condensing engine, on the Friekart system, built by the Société Cockerill, at Seraing, which drives direct a Pieper flywheel dynamo of 600 h.p., at a speed of 80 revolutions per minute. The dynamo is wound for a pressure of 500 volts. Every provision is made in the engine-house for a second section of 600 h.p., of a similar character to the first.

The water from the Meuse, situated at a distance of 2,700 metres from the generating station, is pumped to the works by a 45-h.p. motor, and the current is further utilised in operating two electric wharf cranes for loading and unloading the boats. The motors laid down at present are of the following sizes : five motors of 1 h.p., seven of 2 h.p., six of 3½ h.p., six of 5 h.p., four of 7 h.p., two of 10½ h.p., four of 14 h.p., two of 45 h.p., and one of 64 h.p. It is now proposed to add the following motors : one motor of 80 h.p., one of 14 h.p., five of 1 h.p., and one of 10 h.p. The current is taken from the main generator to the main power switchboard, and is carried through 18 circuits to distributing boards in the works. In addition to the power, there are 75 arc lamps and 500 incandescent lamps in the works. As a tension of 500 volts is too high for the latter, a continuous-current transformer is used which reduces the pressure to 100 volts. During the daytime this transformer charges a battery of accumulators.

The motors drive, amongst other things, joiners' shops, forges, fans, machine tools, saws, pumps, lifts, washing machines, crushing machines, brickmaking machines, etc.

Efficiency of the Installation.

The efficiency of the steam-engine is	90	per cent.
,, ,, generating dynamo	90	,,
,, ,, circuits at full load	98	,,
,, ,, motors	86	,,

which gives a total efficiency of 0·685.

Such are briefly the outlines of the Vieille Montagne installation. Electric power installations have also been laid down, and are working most successfully, at the Royal Arms Factory, at Liège, where the coal consumption has been much reduced ; at the works of Messrs. Dietrich and Co., at Luneville, and at the celebrated glassworks of the Val St. Lambert. At this last place there are six motors, 86 arc lamps, and 1,100 incandescent lights. The author thinks that it has now been shown that electricity has passed out of its experimental stage as far as regards its suitability for driving the various classes of works ; and, in conclusion, trusts that these few very unpretentious notes may have proved a source of interest to the members of the Iron and Steel Institute.

THE DOUBLE-TROLLEY SYSTEM.

Shall we come to the double trolley at last? This is the question which Mr. Nelson W. Perry discusses in the *Street Railway Gazette* of July 28, with special reference to the use of the single trolley with rails and earth return, and the damage done to underground conduits by electrolytic corrosion. In the course of the article the author says :

The remedies that have been suggested from time to time, though they seem to have worked well in some cases, have signally failed in others, and even when a success has been claimed it has not infrequently happened that the claimant was mistaken and that a failure was recorded instead of a success. Much faith is pinned to the welded rail as a panacea for the evil of electrolysis, but it has not been proved that the welded rail is practicable. There are strong hopes that it will prove so, but in the only extensive experiments thus far tried—viz., those in Johnstown and Boston—the rails have failed to withstand the contractions due to the rigours of winter. The only alternative left seems to be to keep the current away from the rails entirely—to use the double trolley.

The double trolley is scarcely known outside of Cincinnati. With something like 200 miles of road electrically equipped there is but one road, consisting of about four miles of double track, that uses the single-trolley system.

During a lawsuit brought by the telephone company against the single-trolley road to compel it to cease interfering with its service, the single-trolley road attempted to prove that it could not operate with the double trolley. The double-trolley road was called in to prove that it was really the better system. A comparison showed that the double trolley was operated at less expense than the single trolley, the reason being, as we know now, that the former had at all times as good a return circuit as the outgoing, while with the single trolley the ground return was a very uncertain quantity.

The greatest objection to the double trolley lies in the complications in the switches and cross-overs. This trouble is both mechanical and electrical. When two roads cross each other there is difficulty in insulating the positive from the negative, since in this system they must necessarily

Digitized by Google

cross each other, whereas in the single trolley the two crossing wires are both positive and presumably at the same potential. In the double trolley, too, at a crossing there are four intersections, whereas in the single trolley there is but one. It is also evidently more difficult to insulate the positive and negative sides of the circuit when they are but 12in. or 13in. apart, as in the double trolley, than when they are so far separated, as in the single trolley; but as an offset to this the cars on the double trolley are entirely independent of the condition of the track, since it forms no part of the circuit. As a result of all this, the double trolley in suburban districts where it does not intersect other wires has proved itself superior to the single trolley, but in centres where many lines cross and radiate it is at a great disadvantage, both on account of the mechanical and of the electrical difficulties attendant upon the many intersections. These difficulties are not insuperable, however, as in Cincinnati there is one centre—the intersection of two streets—Fifth and Broadway, where two lines run east and west, two run north and south, and there are four curves connecting these four lines together, and on Fountain-square the situation is even still more complicated, yet these are the busiest car centres in the city. The complication of wires—trolley wires, span wires, and pull-off wires—at these points is most unsightly, and greatly to be deplored. A perfect stream of cars, however, is continually passing these points, and doing it apparently without trouble. But the water and gas mains are safe, and I believe this is the only way to make them so. There may be other partial remedies which will postpone the day of reckoning, but this seems to be the only radical cure.

THE PACIFIC CABLE QUESTION.

In previous issues, references were made to the Intercolonial Conference at Ottawa, and to the resolutions passed at the various meetings. In this connection, the following article which is reproduced from yesterday's *Times* will be of interest:

The large proportion of time spent by the conference in discussing the question of the Pacific cable furnishes probably a just measure of the interest felt in the scheme. With one exception, to be referred to later, there was practical unanimity of opinion, in spite of all that Sir John Pender has written, as to the need which exists for the cable. The debates brought out the relation of the various colonies to the question. Canada's direct interest in the cable is perhaps less than any of the other communities concerned. Both for strategic and for commercial purposes her present telegraphic connection with the centre of the Empire is cheap and sufficient. But, in pointing this out, the Minister of Finance added: "The unity of the Empire, the security of all its parts, the interdependence of those parts are articles which have worked themselves into the creed of every Canadian." For this reason alone Canada would support the cable energetically. Besides, it is now an accepted axiom that trade follows the cable as well as the flag, and, though the Pacific trade of the Dominion is still chiefly prospective, confident hopes are entertained about its development. The actual interest taken in the line by Canadians is therefore great, and justifies the action of the delegates from the other colonies in giving to the Dominion, as they did at the close of the conference, a practical leadership in pushing forward the work.

Australia's concern in the cable is more direct, and is based on both commercial and defensive considerations. She already spends immense sums in keeping up telegraphic communication with Europe, and the expenditure steadily increases. The people have, therefore, a deep commercial interest in the cheaper cable rates which it is believed the new line will give. Besides this, Australia dreads isolation in time of war, and isolation seems not only possible but probable so far as existing lines are concerned. To no part of the Empire does a remark made during the conference by Sir Charles Mills apply more closely than to Australia. Someone had said that even a Pacific cable, though remote and laid in deep water, might be cut in war as well as the lines which cross Europe and Asia. The Agent-General for the Cape replied that if the line remained intact only long enough to convey the declaration of war it would amply repay the expense of building it.

Once more, if there is to be a cable across the Pacific, Australia wishes it to be British. More than one delegate pointed out that the beginning made by the French in laying a line 800 miles long to New Caledonia, and by the United States in surveying the route from San Francisco to Hawaii, opens up prospects which Australians do not like to contemplate. It was remarked during the conference that, even if Canada and Australia abandoned the project, the cable would still probably be built, and so it might easily turn out that, while the Empire would lose much, the Eastern Extension Company would gain nothing, should its present opposition to the cable prove successful.

The only distinct note of Australian opposition therefore came from Mr. Playford, who was naturally bound to present in the strongest light he could the great sacrifices which South Australia had made to complete connection with Europe by building the trans-continental line, and the risk she runs of losing more heavily in the future than in the past if a rival route be established. Everybody admitted the weight of his argument in these particulars, and the feeling was general that the position of South Australia should, in any new scheme, receive careful consideration.

Mr. Playford went further than merely to state the South Australian view of the situation, and he marshalled with much skill the various criticisms which have been made upon the scheme—the uncertainty about expense; the difficulties which are likely to be met with in unknown seas, and in working the cable over long ocean spaces; the fact that the hydrographer to the Admiralty has apparently taken up an attitude of hostility to the plan for a cable, while no military man of acknowledged authority has yet given a decisive official opinion upon its strategic valve. All this, he said, was pointed out in order that the conference might rightly measure the task it was undertaking, and the cost. But he added that, if it were proved that the cable is required for Imperial and public purposes, then he was instructed by his Government to say that South Australia would not oppose it, but would only ask that the risks which the colony might incur would be as far as possible minimised. The significance of this qualification to Mr. Playford's opposition is manifest.

South Africa is not so directly interested in the cable as Canada and Australia. Sir Charles Mills and Sir Henry de Villiers, however, expressed their belief in the national importance of the line. They also suggested a resolution, which was adopted, looking to the ultimate addition to the cable equipment of the Empire of a line from Australia to the Cape.

Mr. Hoffmeyr was not present during the debate on the cable. He afterwards mentioned to me a view marked with his usual originality and boldness of thought. He claimed that for an Empire such as ours the question of cable construction should be lifted above the range of merely commercial considerations. A Royal Commission should be appointed to report on what lines are required to make the national position strategically complete. This might involve connection, not merely across the Pacific or Indian Oceans, but with remote points like St. Helena, Ascension, and West Indian or East Indian Islands, in order to give effectiveness to naval operations and combinations. The necessities of national defence being settled on definite principles, the lines required should then be constructed at the common expense. Had Mr. Hoffmeyr been present at the cable debate he would have urged upon the conference this view, which it seems well to put on record here.

The relation of the United Kingdom to the question necessarily came up for consideration. Mr. Foster expressed what seems to have been the general opinion of the conference when he claimed that, in view of the interests concerned, it was not unfair nor unreasonable to ask for the support of the Imperial Government. Sir Henry Wrixon pointed out that the outward communication by post or telegraph from a great centre like Britain was known to be greater than the inward, and so the United Kingdom had the greater interest in cheap cable rates, to say nothing of the utility of the alternative route for defensive purposes.

After the criticisms of Sir John Pender had been carefully analysed by Mr. Fleming, Mr. Bowell, and others, the views of the conference finally became crystallised into three resolutions, the first of which affirmed the desirability of constructing a Pacific cable free from foreign control; the second asking the Imperial Government to undertake the survey of the route on the understanding that the expense should be equally divided between Canada, Australasia, and the United Kingdom; and the third requesting the Canadian Government to use its efforts to push forward the scheme and carry out the wishes of the conference.

Everybody agreed that the survey is a necessary preliminary to final and decisive action. As the conference was closing, Mr. Siemens, who had hurried to Ottawa after laying the last Atlantic cable, placed before the delegates his opinion that, with the new apparatus now brought to perfection, it is possible to lay a cable in unknown and varying depths, and that the work is quite feasible with the knowledge of the route already existing. But it is doubtful if this opinion, even if placed before the conference earlier, would have influenced the final decision.

There can be no doubt that the agreement of the colonies to share in the expense of survey and the determination expressed to push forward the scheme, advance the question of the cable much beyond the position in which it was left by the conference of 1887. A fair degree of energy on the part of the colonies, and reasonable co-operation by the mother land, should soon bring the matter to a final issue.

What has been said would be incomplete without reference to a discussion upon the method of construction brought up by Mr. Thynne in a resolution which proposed that the cable should be undertaken as a joint national and public work. The delegates of New South Wales and of New Zealand were strongly opposed to the work being done otherwise than by means of a private company. Mr. Playford as warmly supported the resolution, which had the endorsement, I think, of a majority in the conference, though two or three of the members looked upon the question with an open mind. The resolution was finally withdrawn as being premature, but the discussion and difference of opinion which it evoked have interest, inasmuch as the question is one which must be settled at an early stage of the enterprise.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

STREET-LIGHTING WITH INCANDESCENT LAMPS.

There is hardly any need at the present day to deal with and explain the greater cost of arc lamps for the purpose of street-lighting as compared with the ordinary expenditure upon gas lights to an extent hitherto considered sufficient. Perhaps in a few country towns there may yet be local authorities and officials who require convincing upon the subject, and who when asked to authorise the payment of £25 or £26 per annum for each and every arc lamp installed in the streets, instead of an eighth of that amount per gas lamp, previously used, cannot understand without much and lengthy argument that the extra light given in the first instance (say, fifty times as much) is well worth the greater expenditure. Speaking generally, however, it may be said that not only municipal authorities and officials, but even the outside public have begun to realise these facts, and assess them at their proper value.

There is, nevertheless, a great deal to be said upon the subject from an economical standpoint, and all those who have to decide the question of improved street-lighting will do well to bear constantly in mind the great difference that exists between the amount and quality of illumination required for the various thoroughfares of a single town or city. Arc lamps must without doubt have extensive employment in the main streets; their additional expense is more than counterbalanced by the greater light afforded, but when the side streets and less important thoroughfares are considered, the lighting authorities may well feel somewhat perplexed as to their most advisable action.

Efforts, of course, are made to overcome the difficulty by fixing the arc lamps on main streets at or near the corners of side streets, so that their more powerful light may at least shine as far as possible down the latter; but this can only be done to a limited extent, and not at all in streets at a distance from the electric light mains. What is to be done with these cases? Several suggestions have been made from time to time, but the real solution of the problem seems to turn upon the introduction of a satisfactory method of lighting incandescent lamps in series, just as in the case of the arc lamps now employed.

Obviously it would not altogether be safe or advisable to work incandescent lamps for street-lighting from the ordinary low-pressure mains that serve for house-lighting, etc.; the expense of running separate low-pressure wires—with the lamps in parallel—and the difficulty of maintaining full pressure over a scattered area, both seem to point out a series system as being the more likely to give satisfaction with economy. We should not be surprised at any time to hear of a favourable plan being thus devised; indeed, whisperings have already reached us that experiments will very soon pass into experience, and that we may see a system of this type at work in connection with the largest street-lighting plant now in operation.

In this connection, then, it is peculiarly interesting to note that a special committee of the Islington Vestry has reported to that body upon the entire

Digitized by Google

question of street-lighting throughout its district, coming to the conclusion that a system of arc lamps along the main roads will cost but little, if any, more than gas, whilst the illumination of the streets will be greatly increased, and consequently also the thoroughfares made more attractive and trade generally developed in the neighbourhood. We congratulate the committee on coming to such a conclusion, obvious as it may be to the well informed; and whether the cost of arc lighting as thus proposed be much the same as or greater than that of gas, we are quite sure that after once installing such a system there will afterwards be no question of ever doing without it.

The committee appears to be quite awake to the extra cost involved, and propose to reduce it slightly by switching off, say, half the street lamps during the long hours of the night, or by replacing the arcs with incandescents. Whether this latter proposal would effect any great saving whatever is not too clear to our minds, though obviously the horse-power expended would be less. That, however, is not the only item involved.

To find a local authority in readiness to consider the use of incandescent lamps for street-lighting at all, is decidedly an important sign of the times. If such a method is of service in main streets, it must be still more so in the secondary thoroughfares: and we shall expect to see great progress made soon in deciding the question. After all, it only means the devising of a reliable and efficient cut-out for incandescent lamps—automatic in action, cheap, and simple to construct.

HORSES FOR SALE.

There has been quite enough of mere "talk" concerning the better development of electric traction in this country for some years past, and we plead guilty ourselves to some of it, although the purpose behind any such expressions has been wholly the consideration of electrical interests. Less than a week ago, however, the Imperial Tramways Company held its usual half-yearly meeting, and the chairman introduced some very important statements into his speech.

It will be remembered that this company owns a number of separate enterprises in different districts, amongst these being the Dublin Southern District Tramways, which reach from Dalkey, through Kingstown, to Dublin. Privy Council and parliamentary powers for the use of electric traction on the lines, with an extension of the system and assimilation of gauge, were obtained some time ago (after no little opposition from the Dublin, Wicklow, and Wexford Railway, who obviously feared the effects of wholesome competition), and since that time the directors have been completing the necessary financial and other arrangements for the heavy work thus taken in hand.

A further cause of delay has been the discussion and settlement before the Board of Trade of standard rules for the erection and working of electric lines: for obviously it was unwise to take active steps in the matter before knowing what would be required by the authorities. Now, however, the matter is definitely settled, and it is expected that by next summer we shall see a double-track electric tramway stretching along the whole length of eight miles between Dublin and Dalkey.

The contract is to be carried out by the British Thomson-Houston, Limited, at a total cost of £70,000 for laying the double line, rearranging the present terminal depôt as a power station, and equipping the line with an overhead conductor system and motor cars. This means that the present capital of the Dublin Southern District Tramway Company is to be doubled, since the ordinary shares—all held by the Imperial Company—have a nominal value of £70,000. On the total capital of £140,000—half of which now issued bears preferential charges, the other half being represented by the ordinary shares—it is confidently expected that profitable dividends will be paid, owing to the greatly diminished working expenditure and the correspondingly increased receipts due to a quicker and more frequent through service. Those engaged in the work have, at any rate, the courage of their convictions in this respect, as they propose themselves to find all the debenture or preferential capital: the Imperial Company contribute £10,000 in cash and the contractors—both electrical and permanent way, etc.—offer the balance.

We enter thus minutely into the particulars of this enterprise, not only because it bids fair to be the most important of its kind yet undertaken, but also by reason of the fact that the chief obstacle in developing other lines elsewhere has been the apparent impossibility of arranging satisfactory financial conditions. All the more credit, then, is due to those in charge of the Dublin enterprise for being able to secure the construction of their lines without having to wait for public investors to think so highly of electric traction as to offer the necessary capital. It shows decided confidence in the prospects of the change, and they deserve to reap the reward of increased traffic at less working cost.

Another event that to our mind tends also to show the flowing tide in electric traction development is the recent opening of the Douglas and Laxey Electric Tramway in the Isle of Man, particulars of which were given in our last issue. This being an absolutely new line, the title given to our remarks does not apply to it in the manner that will probably be the case very soon at Dublin, but in other respects—actual length of track, novelty of constructive details, etc.—the Laxey tramway has features of most striking interest. It may be regarded as embodying all the improvements yet developed on sound mechanical lines, not the least of these being the use of cross-bars instead of the clumsy device of a trolley wheel for making contact with the overhead conductor.

The ball is now, we think, fairly set rolling in electric traction matters: just how far and how fast it will go remains yet to be seen. We may hope, at any rate, that it will "gather no moss."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LOWRIE'S INTRAPOSED SYSTEM.

SIR,—I regret that owing to the holidays I did not see Mr. Faber's letter in time to reply to it in your last issue. I am entirely at issue with the opinion he has expressed respecting my controller switch, and he is in error in supposing that I would patent an invention before I had practically tested and proved it. My system is—as to its several parts, and as a whole—the outcome of practical work.—Yours, etc.,

W. LOWRIE.

August 17, 1894.

SOME OF THE ELECTRICAL COMPANY'S MANUFACTURES.

Two or three weeks ago we referred to the new manual brought out by the Electrical Company, of 122 and 124, Charing Cross-road, W.C., who are the English representatives of the Allgemeine Elektricitäts Gesellschaft, of Berlin. A selection from this manual of some of the company's manufactures should prove interesting at the moment. Fig. 1 shows the S-type of direct-current dynamo which is made in various sizes, is of solid construction, and of high efficiency. The dynamos run smoothly and without sparking, and they are arranged for belt driving. Of the various kinds of regulating apparatus made by the company for dynamos, the automatic shunt regulator represented in Fig. 2 is an example. The regulator is constructed according to the Thury system. In Fig. 3 is shown an electric lift. For passenger lifts the motor shaft is coupled direct to the

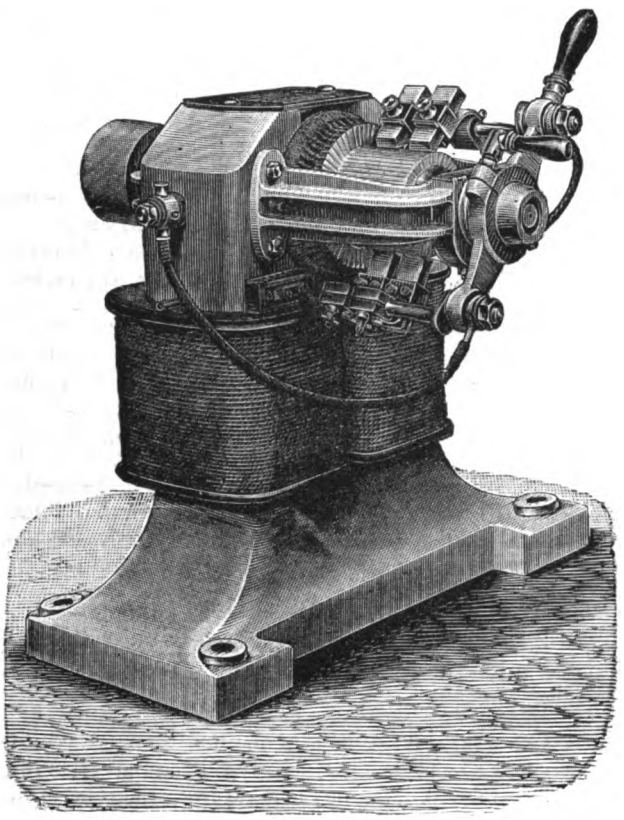

FIG. 1.

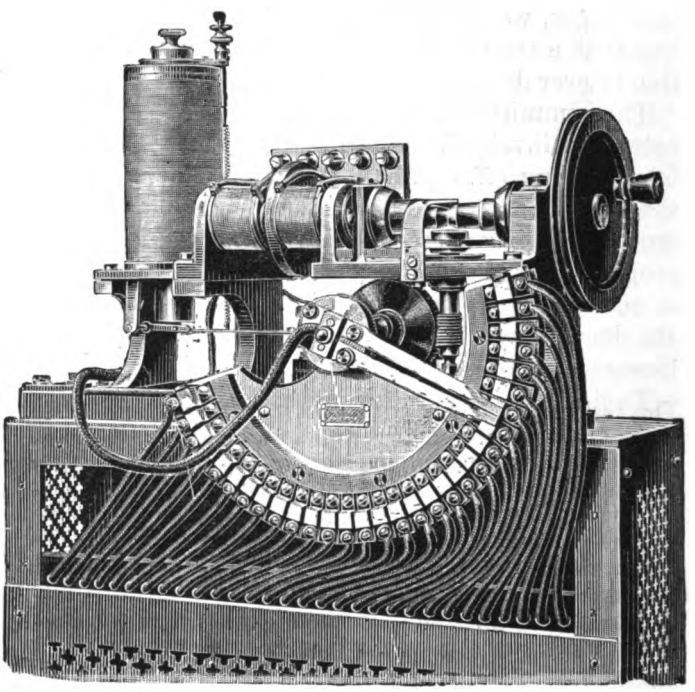

FIG. 2.

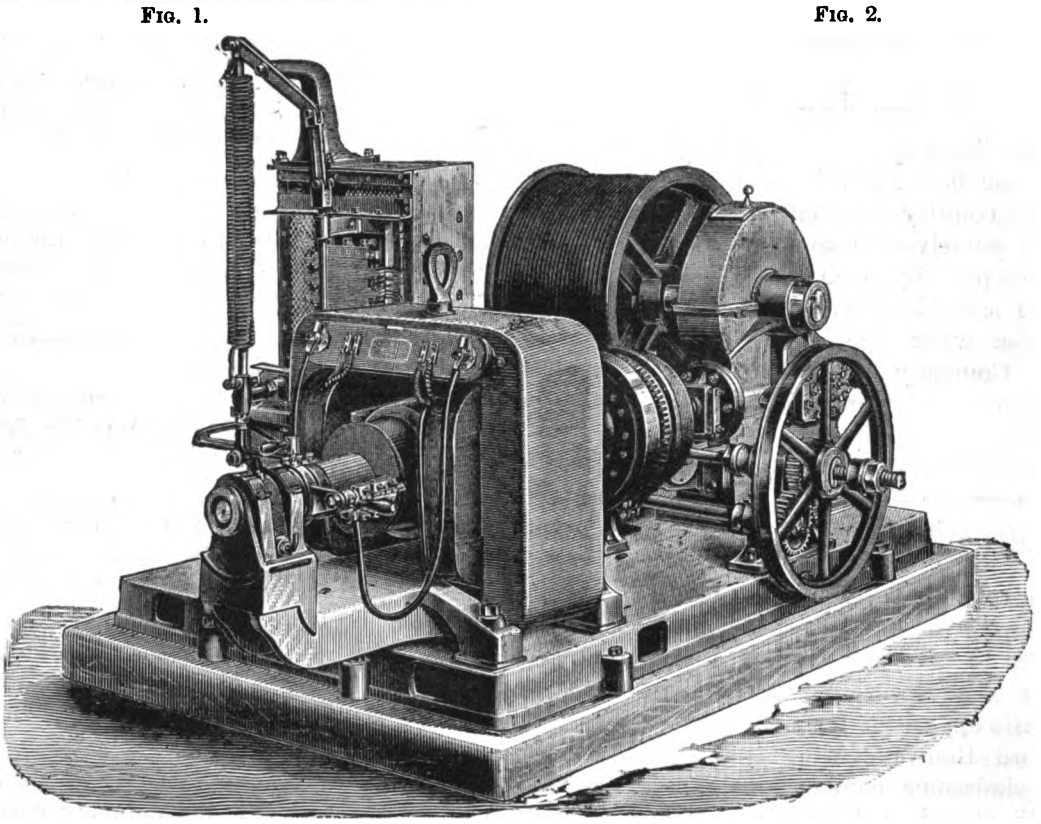

FIG. 3.

Digitized by Google

worm shaft, but in the case of lifts for goods the motor either drives the worm by means of wheels, or the worm shaft by means of a bevelled countershafting. A starting resistance is provided to set the motor in operation, being connected with the governor by bevel wheels and pulleys.

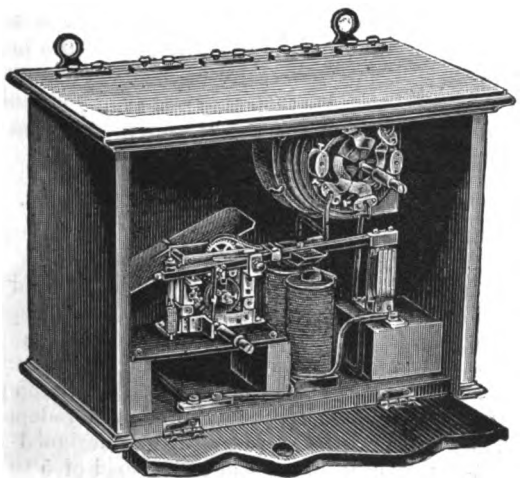

FIG. 4.

This resistance can be arranged with a current-reversing apparatus, if no bevel gear is fitted, to enable the motor to run to the right or left, thereby effecting the upward or downward movement of the lift. A further arrangement is provided for automatically throwing the motor out of gear when the lift attains its final position. The lifts are constructed for double carrying capacity, and for the use of double counterweight ropes. Fig. 4 represents an apparatus for the intermittent lighting of staircases. It comprises a switch which closes and breaks a circuit automatically after a given time—three or five minutes, according as it is set.

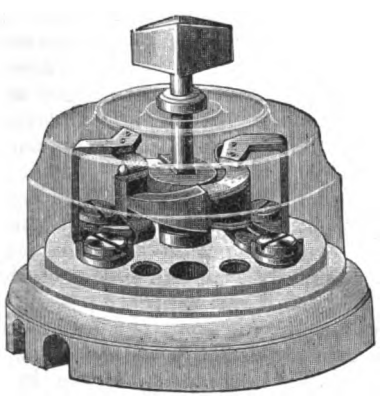

FIG. 5.

By pressing a button the clockwork of the apparatus is set in operation and the lights are switched on. The last illustration shows the A.E.G. switch.

SOME FACTS ABOUT POLYPHASE MOTORS.*

BY LOUIS BELL.

In connection with the long-distance transmission of power, most engineers will, I think, agree with me in the position that alternating-current motors of some kind, and of alternating current, preferably the polyphase variety, are almost a necessity. We have been forced to their use by the exigencies of long-distance service, which compel either the total abandonment of continuous current or its use under very embarrassing conditions.

There has, however, been a tendency to look upon the polyphase motor as a somewhat undesirable resort to which we have been driven by long-distance work. Such, indeed, was my own belief from *a priori* reasoning, and before I had obtained that practical knowledge of the subject which can only come from personal experience both with the design and application of any class of apparatus. By such experience, and by the commercial demands which have been coming in with steadily increasing frequency, I have been forced into taking the position that the polyphase motor is intrinsically preferable to the continuous-current motor for a vast majority of all the uses to which such machinery may be applied.

At present appearances indicate that not only will the polyphase motor displace direct-current apparatus for most long distance transmission plants, but will prove a formidable competitor in all applications of motors to industrial purposes, and this although the polyphase apparatus is the growth of only a few years, while the direct-current motor is the outcome of more than a decade of experience.

We may, then, in instituting a comparison between polyphase and direct-current motors, consider the various properties which a good motor of any kind must necessarily have. Mechanically speaking, we would all agree that it should be simple in construction, strong, not liable to frequent or considerable repairs, convenient in form, and not excessive in weight. As regards its properties, it should, in general, run cool, stand overloading without serious danger, run at a nearly constant speed, or be capable of considerable variation in speed if necessary. It should be capable for certain uses of sudden and violent exertion, and of easily changing its direction of rotation. In a purely electrical way, it should be simple, efficient both at high and low loads, and should not take excessive amounts of current either in starting or in running.

This represents a difficult list of conditions to fulfil with any one motor, but I believe they can be met better by polyphase than by direct-current machines. A direct-current motor, for instance, of a given construction and reasonable weight, cannot run both at a constant speed, independent of load, in a particular case, and at the same time be capable of running at a wide variety of other speeds. It usually will not stand considerable overloads without sparking and at the same time give a fair efficiency at low loads, and so one might go on piling up difficulties. The polyphase motor, too, cannot meet all these conditions with equal success, but examining them one by one you will find that on the whole we can obtain very excellent results.

Taking up seriatim the desirable properties which I have enumerated, and applying them to polyphase motors, we find as regards the first count that their construction is singularly free from complexity. They consist, in general, of two concentric masses of lamination, forming respectively the fields magnet and armature. The armature is assembled on its shaft much as in direct-current machinery, while the field laminations are held together by a clamping spider of very simple construction. The bearings are supported either on end spiders fitted to the field spiders by lathe work only, or on pillow blocks of the ordinary kind. Commutator or commutator connections there are none, nor should there be collecting rings except in rare instances. The armature need be exposed only to low voltages, and should preferably be wound with a comparatively small number of rather massive conductors, united at the ends either by a single plate or by very simple connectors, the latter form being preferable. The field winding is usually in a greater number of coils than is a direct-current field winding, but each coil has a comparatively small number of convolutions, making the total winding by no means complicated.

In lieu of the starting rheostat of the direct-current motor, we have a starting resistance which should preferably be placed within the armature, and consists of a few zigzags of metal united at one end and connected at the other to three or more contact-pieces. A solid collar short-circuiting these contacts, and a forked lever to move the collar, completes the equipment, as I am accustomed to employ it. Its most noticeable feature is that the revolving armature, the most troublesome and delicate part of a direct-current machine, is free from complication, and that it is almost as solid as if it were a solid mass of metal, and scarcely more liable to injury.

*A paper read at the Philadelphia meeting of the American Institute of Electrical Engineers.

Digitized by Google

This very obvious simplicity of construction and mechanical strength is strong evidence of unusual freedom from repairs, and as a result of experience I have found that the induction motor is singularly free of liability to accidents of every kind. I have never succeeded even by the severest kind of experimental work in burning out a field coil or doing any serious injury whatever to a motor, although I have kept some of them on static torque tests in rapid succession for hours at a time, and have held them at rest and poured current through them until the leads burned off, the motor still remaining undamaged. If there is a test of extraordinary severity that I have not applied to induction motors, I have yet to learn of it. These properties are invaluable in commercial work, inasmuch as they practically remove the danger of crippling the motor even under exceptionally unfavourable conditions.

As regards the convenience of the form of polyphase induction motors, I think an inspection of any of the types which have been brought out will render argument unnecessary.

The magnetic necessities of the case have led all makers of such apparatus in this country and elsewhere to adopt a species of barrel shape as the general outline of the motor, modified only in the proportions of diameter to length, and in the adoption of one form or another of bearing. The tendency of this construction is to bring the centre of gravity of the machine very low, thus ensuring unusual stability and freedom from general vibration. This form, too, enables one to place the motor in almost any position which is convenient in applying it, upside down, as a side bracket, and the like.

The largest installation of induction motors in the world, just put in operation in Columbia, S.C, aggregating over 1,200 h.p., is composed of inverted motors with their bases bolted to the ceiling timbers of the rooms.

As regards weight, the abolition of any sparking limit to the output, and the excellent magnetic material used, might naturally be supposed to lead to motors of unusually light weight, and such is, in fact, the case; 60lb. to 70lb. per horse-power in motors of moderate size is a figure easily reached without any sacrifice of efficiency, and if occasion requires, these limits can be passed with great facility, 25lb. to 30lb. of material per horse-power being quite attainable in large units, while still retaining satisfactory general properties. I must say, however, that for most uses I do not consider extreme lightness either necessary or desirable, although it is important to be able to secure it if necessary. So much for the mechanical character of induction motors.

Electrically speaking, the case is just as favourable. Unless forced to a very large output per pound of weight, an induction motor will run quite cool, at a heating limit, in fact, below that of most direct-current machines of similar weight and output. This advantage is mainly due to the very substantial character of winding which can be conveniently employed, and to the fact that the winding is distributed so that the losses in the copper are not localised, while the laminated character of the structure facilitates thorough ventilation. This freedom from excessive heating indicates that the polyphase motor can stand considerable overloading without any serious results, and experience has shown this to be the case. The worst that can really happen is that the motor may fall out of synchronism when the load is sufficiently great, thereby blowing the fuses in the primary line.

As sparking is obviated in this type of machine, it can readily be rated at such output as will give a proper limit of heating, and this output will in most cases allow from 30 to 60 per cent. of overloading before the machine will drop out of step. A wider range than this can be obtained if desirable, which it is generally not.

The limit of possible overloading fixes in a general way the possible static torque that can be obtained from a given machine, and this is apparently purely a matter of convenience in design, anything that can reasonably be required being quite attainable. There is no special difficulty in arranging polyphase motors for a starting torque four or five times the running torque, although this would be unnecessary except for severe hoisting and tramway work. At running torque the starting current taken may readily be no greater than the running current. From this it will readily be seen that a properly-planned polyphase motor is easily capable of very great and violent exertions in a case of necessity. It will even endure complete reversal under full load within 10 or 15 seconds on motors of ordinary sizes, this time being sufficient for the machine to pass from full load in one direction to full load and speed in the other direction. This reversal is, as is well known, accomplished simply by reversing any two of the primary wires, the effect being to rotate the field in the opposite direction from the armature, thus causing an enormous rate of cutting lines of force, and consequently immense effort, causing the motor to stop and reverse.

Speed Variation in Polyphase Motors.

This subject has been for the most part in rather a hazy condition up to the present time. The induction motor has been generally known as nonsynchronous, and such, indeed, it is. The name, however, has been frequently used in ignorance of the fact that an induction motor always tends towards synchronous running.

Under ordinary conditions the polyphase induction motor can be made to run at nearly constant speed independent of load, resembling in this respect a well-designed shunt motor. A variation from no load to full load of 5 to 6 per cent. in speed would represent ordinary good practice, either in a shunt motor or a polyphase one, this limit being exceeded only in small motors or types which may be regarded as special. It is by no means difficult, however, so to design a polyphase motor that the speed shall possess very remarkable uniformity. This condition has been valuable in the Columbia plant previously alluded to. In this case tests of 17 motors showed a maximum variation in speed from an output of 75 h.p. to friction load of the motor, of only 2·2 per cent., individual motors showing slighter variations down to 1½ per cent.

The task of these particular motors is driving a cotton mill, hence the necessity for uniform speed. And this uniformity in speed is not greatly affected by variations in voltage, which would be quite sufficient to cause considerable speed variation in a shunt-wound motor; in fact, the induction motor is remarkably insensitive to moderate variations in voltage, unless it is heavily loaded. This uniformity in speed has frequently been urged as an objection to the induction motor, barring its employment in cases where speed variation is necessary. This point is not well taken.

The induction motor cannot be made successfully to run at reduced speed by varying the primary voltage. Under these circumstances the output of the machine falls off somewhat more rapidly than the square of the voltage, so that only trifling speed variations are possible. It is a fact not generally known, however, that the speed of a polyphase motor can be varied with the same facility and within the same wide range as is possible in the case of a series-wound continuous-current machine, such as a railway motor. This is accomplished in the induction motor by a rheostat in the secondary circuit, just as it is accomplished in the series motor by a rheostat in the main circuit. Thus equipped, the two machines behave almost exactly alike. The speed at constant torque can be made to vary from full speed down to almost no speed, thus simulating the action of the series motor in the closest possible fashion. At any given speed an increase or decrease of the torque will decrease or increase the speed substantially alike in both classes of motors. In both, too, the efficiency is initially similar, and falls off in practically the same ratio. A non inductive resistance is necessary in case of the polyphase motor, an inductive one throwing the armature current so far out of phase as to interfere with the proper action of the motor.

Fig. 1 gives an excellent idea of the behaviour of a polyphase motor with resistance in the secondary circuit.

Curve A shows the speed and output of a certain motor under these circumstances. It was a four-pole machine operated at 50 cycles per second, and the initial speed was reduced to 1,400 by the resistance of the leads reaching across the room to the rheostat, composed of loops of manganin strip which could be systematically varied. It will be seen that the word curve is almost

Digitized by Google

a misnomer, the ratio between the speed and output at constant torque being almost a linear function, even when the speed fell to as low as 150 revolutions per minute. It was not carried lower than this only because of lack of adaptability in the rheostat. No series motor could show a more satisfactory result.

Curve B shows the power factor under these varying conditions. It is high at all loads and speeds, varying slightly, with a maximum at about half speed.

Curve C shows the variation in current. This, as can be seen, is almost constant, falling off slightly at the lower speeds, the voltage being uniform throughout the test.

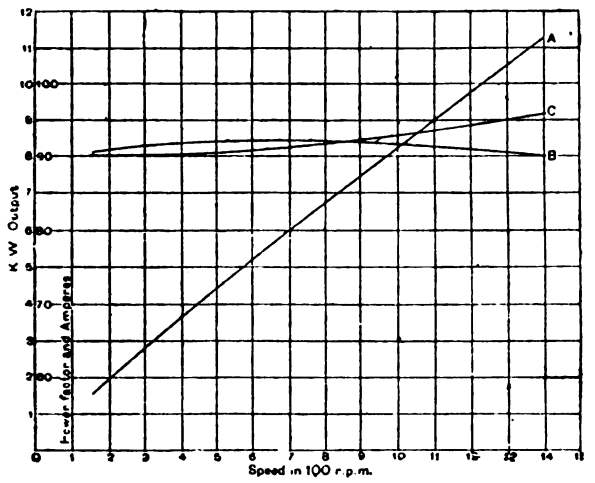

FIG. 1.

Speed variation by this method is not as efficient as might be wished, but still compares favourably with that obtained in a series motor with rheostatic control. Some modified methods of control promising a somewhat better efficiency have been suggested, but it seems probable that in the net result we shall find that continuous-current and polyphase motors are about on a par in this respect. It should be noted that in continuous-current motors, speed variation by weakening the field is only practicable within a very limited range, and requires an abnormally heavy motor. I think that with a similar change in design the polyphase motor could be made to operate nearly as well by change in its field strength. An efficient speed variation through a very wide range is attainable in either class of machine only by extraordinary means, as an elaborate combination of direct-current machines, or frequently changing devices in the polyphase machines. From what has been said it will be apparent that the polyphase motor is perfectly capable of a complete control of speed on the same terms generally obtained with continuous-current motors.

(To be continued.)

EXPERIMENTS FOR IMPROVING THE CONSTRUCTION OF PRACTICAL STANDARDS FOR ELECTRICAL MEASUREMENTS.

Report of the Electrical Standards Committee of the British Association, consisting of Prof. CAREY FOSTER (chairman), LORD KELVIN, Profs. AYRTON, J. PERRY, W. G. ADAMS, and LORD RAYLEIGH, Drs. O. J. LODGE, JOHN HOPKINSON, and A. MUIRHEAD, Messrs. W. H. PREECE and HERBERT TAYLOR, Prof. J. D. EVERETT, Prof. A. SCHUSTER, Dr. J. A. FLEMING, Profs. G. F. FITZGERALD, G. CHRYSTAL, and J. J. THOMSON, Messrs. R. T. GLAZEBROOK (secretary), W. N. SHAW, and T. C. FITZPATRICK, Dr. J. T. BOTTOMLEY, Prof. J. VIRIAMU JONES, Dr. G. JOHNSTONE STONEY, Prof. S. P. THOMPSON, and Mr. G. FORBES.

APPENDIX.

I.—Report of the American Delegates at the Chicago Conference to the Secretary of State at Washington.

II.—Experiments on the Value of the Ohm, by J. Viriamu Jones.

III.—Comparison of the Standards employed by Prof. Jones with the Standards of the Association, by R. T. Glazebrook.

IV.—Comparison of some of the Standards of the Board of Trade with those of the Association, by J. Rennie.

V.—Values of Certain Coils belonging to the Indian Government, by E. O. Walker.

VI.—On the Specific Resistance of Copper and of Silver, by Rev. T. C. Fitzpatrick.

The work of testing resistance coils at the Cavendish Laboratory has been continued. A table of the coils tested is given.

The committee regret that the insulation of some of the coils referred to in their last report which had been selected for the new standards of resistance, as defined by the resolutions adopted at Edinburgh, has proved defective. Traces of acid have been discovered in the paraffin with which the coils were filled. The two one-ohm standards of the association (Report 1893, p. 3), as well as two of the one-ohm standards of the Board of Trade (Report 1892, p. 3), were found in January last to have so low an insulation resistance between the coil and the case as to be useless. Thus the labour spent in the testing of these coils has been wasted; much of it will need to be done again.

The insulation of some of the other standard-ohm coils is not satisfactory; the single-ohm standards have, therefore, been remade, and the others are being refilled with carefully selected paraffin. The original B.A. units have not, so far as comparisons between them can show, changed their values during the year, and one set of new ohm standards also have shown no sign of change.

The committee print, as an appendix to the report, the report of the proceedings at the international congress at Chicago presented to the Secretary of State at Washington by the American delegate to the conference.

During the year Prof. J. V. Jones has determined by the aid of his Lorenz apparatus the absolute resistance of certain wire coils of about ·1 ohm. These have been compared with the standard of the association by the secretary. An account of these experiments is contained in Appendices II. and III. The resistance standards of the association have been compared with

Digitized by Google

those of the Board of Trade by Mr. Rennie and the secretary. Details of this comparison will be found in Appendix IV., while in Appendix V. is given by Mr. E. O. Walker an account of a comparison between five coils belonging to the Indian Government, which have been 24 years in India, and Dr. Muirhead's standards. Mr. Fitzpatrick has continued his work on the specific resistance of copper, and has drawn up a table (see Appendix VI.) reducing to the same units experimental results recently obtained by various observers. Appendix VII.* contains an account of a special form of standard of low resistance devised by Prof. Jones. In consequence of the difficulty met with in the insulation of some of the coils, it was thought well to defer the purchase of other coils for which the grant of £25 was obtained last year. The committee are of opinion that it is desirable to complete their set of standards by obtaining from Germany certified copies of the standards of the Reichsanstalt. They recommend therefore that they be reappointed, with the addition of the name of Mr. Rennie, with a grant of £25; that Prof. G. Carey Foster be chairman, and Mr. R. T. Glazebrook secretary.

APPENDIX I.

Report of the Action of the International Electrical Congress held in Chicago, August, 1893, in the Matter of Units of Electrical Measure.

Washington, D. C., November 6, 1893.

The Hon. W. Q. Gresham,
Secretary of State, Washington, D.C.

SIR,—The undersigned, having been designated by you on May 12, 1893, as delegates to represent the United States in the International Electrical Congress to be held in August at Chicago, beg to submit herewith a brief report showing the definitive action of said congress in the matter of defining and naming units of electrical measure. The consideration of this important subject was left to what was known as the "Chamber of Delegates" of the congress, consisting only of those who had been officially commissioned by their respective Governments to act as members of said Chamber. After conference and correspondence with the leading electricians of Europe, it had been agreed that the maximum number of such delegates to be allowed to one nation should be five, and this number was allotted to the United States, Great Britain, Germany, and France. Other nations were allowed three or two, and in some instances one. Delegates present and taking part in the discussions and action of the Chamber were as follows:

Representing the United States.—Prof. H. A. Rowland, Johns Hopkins University, Baltimore, Md.; Dr. T. C. Mendenhall, superintendent of U.S. Coast and Geodetic Survey, and of Standard Weights and Measures, Washington, D.C.; Prof. H. S. Carhart, University of Michigan, Ann Arbor, Mich.; Prof. Elihu Thomson, Lynn, Mass.; Dr. E. L. Nichols, Cornell University, Ithaca, N.Y.

Representing Great Britain.—W. H. Preece, F.R.S., engineer-in-chief and electrician, Post Office, England, president of the Institution of Electrical Engineers, London; W. E. Ayrton, City and Guilds of London Central Institution, Exhibition-road, London; Prof. Silvanus P. Thompson, D.Sc., F.R.S., principal of the City and Guilds Technical College, Finsbury, London; Alex. Siemens, 12, Queen Anne's-gate, Westminster, London, S.W.

Representing France.—E. Mascart, membre de l'Institut, 176, rue de l'Université, Paris; T. Violle, professeur au Conservatoire des Arts et Métiers, 89, Boulevard St. Michel, Paris; De la Touanne, telegraph engineer of the French Government, 13, rue Soufflot, Paris; Edouard Hospitalier, professeur à l'École de physique et de chimie industrielle de la ville de Paris; vice-president de la Société internationale des Eléctriciens, 6, rue de Clichy, Paris; Dr. S. Leduc, 5, quai Fosse, Nantes.

Representing Italy.—Comm. Galileo Ferraris, professor of technical physics and electrotechnics in the R. Museo Industriale, Turin, Via Venti Settembre, 46.

Representing Germany.—H. E. Hermann von Helmholtz, präsident der Physikalisch-technischen Reichsanstalt, professor a. d. Universität, Berlin, Charlottenburg bei Berlín; Dr. Emil Budde, Berlin N.W., Klopstockstrasse 53; A. Schräder, Regierungsrath, Mitglied des Kaiserl. Patentamts, Berlin; Dr. Ernst Voit, professor an der technischen Hochschule, München, Schwanthalerstrasse 73-3; Dr. Otto Lummer, Mitglied der Physikalisch-technischen Reichsanstalt, Charlottenburg, Berlin.

Representing Mexico.—Augustin W. Chavez, city of Mexico.

Representing Austria.—Dr. Johann Sahulka, Technische Hochschule, Wien.

Representing Switzerland.—A. Palaz, professeur, Lausanne; René Thury, ingénieur, Florissant, Genève.

Representing Sweden.—M. Wennman, Byrachef i Rougle Telegrafstyrelsen, Stockholm.

Representing British North America.—Ormond Higman, electrician, Standards Branch, Inland Revenue Department, Ottawa.

His excellency Dr. H. von Helmholtz was made honorary president of the congress; Dr. Elisha Gray, of Chicago, was chairman of the General Congress; and Prof. H. A. Rowland, of Baltimore, was president of the Chamber of Delegates.

Meetings of the Chamber continued during six days, at the end of which its members unanimously agreed in the adoption of the following resolution:

Resolved, That the several Governments represented by the delegates of this International Congress of Electricians be, and they are hereby, recommended to formally adopt as legal units of electrical measure the following: As a unit of resistance, the *international ohm*, which is based upon the ohm equal to 10^9 units of resistance of the C.G.S. system of electromagnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass, of a constant cross-sectional area and of the length of 106·3 centimetres.

As a unit of current, the *international ampere*, which is one-tenth of the unit of current of the C.G.S. system of electromagnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, and in accordance with accompanying specifications,* deposits silver at the rate of 0·001118 of a gramme per second.

As a unit of E.M.F., the *international volt*, which is the E.M.F. that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampere, and which is represented sufficiently well for practical use by $\frac{1000}{1434}$ of the E.M.F. between the poles or electrodes of the voltaic cell known as Clark's cell, at a temperature of 15deg. C., and prepared in the manner described in the accompanying specification.†

As a unit of quantity, the *international coulomb*, which is the quantity of electricity transferred by a current of one international ampere in one second.

As a unit of capacity, the *international farad*, which is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity.

As a unit of work, the *joule*, which is equal to 10^7 units of work in the C.G.S. system, and which is represented sufficiently well for practical use by the energy expended in one second by an international ampere in an international ohm.

As a unit of power, the *watt*, which is equal to 10^7 units of power in the C.G.S. system, and which is represented sufficiently well for practical use by the work done at the rate of one joule per second.

As the unit of induction, the *henry*, which is the induction in a circuit when the E.M.F. induced in this circuit is one international volt, while the inducing current varies at the rate of one ampere per second.

The Chamber also voted that it was not wise to adopt or recommend a standard of light at the present time.

A more complete report of the operations of the Chamber will shortly be forwarded. This brief *résumé* of its definite action in reference to the matter of units is now submitted to facilitate the prompt dissemination among representatives of foreign Governments of the important results of a congress of whose success and fruitfulness the United States may justly be proud.

H. A. ROWLAND. ELIHU THOMSON.
T. C. MENDENHALL. E. L. NICHOLS.
H. S. CARHART.

---

* We are unable to publish this in this issue.

* In the following specification the term silver voltameter means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time average of the current, or if the current has been kept constant, the current itself, can be deduced. In employing the silver voltameter to measure currents of about one ampere, the following arrangements should be adopted: The cathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10 centimetres in diameter and from 4 to 5 centimetres in depth. The anode should be a plate of pure silver some 30 square centimetres in area and 2 or 3 millimetres in thickness. This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the cathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing-wax. The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water. The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

† A committee, consisting of Messrs. Helmholtz, Ayrton, and Carhart, was appointed to prepare specifications for the Clark's cell. Their report has not yet been received.

APPENDIX II.

On a Determination of the International Ohm in Absolute Measure.

BY PROF. J. V. JONES, F.R.S., PRINCIPAL OF THE UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The apparatus for the absolute measurement of electrical resistance in my laboratory at Cardiff was completed in 1890, and I first used it for the determination of the specific resistance of mercury in absolute measure (*Phil. Trans.*, 1891, A). This determination was made by direct measurement on a mercury column contained in a trough of paraffin wax. The results of five complete sets of observations were as follows :

94103
94074
94093
94045
94021

The mean of these is 94067 ; and the extreme variation from the mean is 46, or about four parts in 10,000.

I suspected that much of the variation was due to the paraffin trough, the temperature of which varied slightly (about half a degree) during the observations, and was not accurately measurable owing to the low conductivity of the material. With variation of temperature there was variation of breadth, and the breadth of the trough entered as a primary factor into the calculation of the specific resistance.

When I proceeded to use the apparatus for the measurement of low-resistance standards of solid metal this was conclusively shown to be the case. I brought a set of measurements made on such a standard under the attention of the section last year (at Nottingham), in which the extreme variation from the mean was only about one part in 12,000.

This may be taken to be the normal performance of the apparatus, and seeing that it is an instrument of such precision it seemed to me of interest to determine by the use of solid metal standards the relation between its indications and the results obtained by other observers for the value of the ohm.

With this end in view I obtained four coils from Messrs. Nalder Bros.—two platinum-silver 10-ohm coils, and two manganine tenth-ohm coils. Mr. Glazebrook has measured them in terms of the international ohm ; and I am much indebted to him for the pains he has been kind enough to take in making the determination. The following table gives their resistances and temperature coefficients :

Coil number.	Resistance in I. O. (Glazebrook).		Temperature coefficient (Nalder).
3,873	9 9919	at 14° 8 C.	·000300
3,874	9 9926	,, 14° 9 C.	·000276
4,274	·100050	,, 15° 2 C.	·000013
4,275	·100053	,, 15° 2 C.	·000013

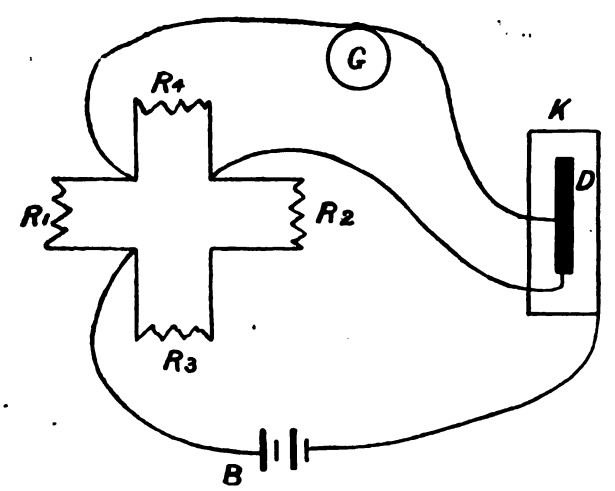

FIG. 1.

These coils were arranged in manner similar to that adopted by Lord Rayleigh in his determination of the ohm by the method of Lorenz (see Fig. 1). If there is no current through the galvanometer, there is equality between the E.M.F. due to the rotation of the disc in the field of the standard coil and the E.M.F. due to the current through R_4 ; and we have, if R_1, R_2, R_3, R_4 are the values of the four resistance coils in international ohms, and if x is the value of the international ohm in absolute measure,

$$\frac{R_2 R_4 x}{R_1+R_2+R_3+R_4} = M n,$$

where M = the coefficient of mutual induction of the standard coil and the circumference of the disc, and n = the rate of rotation of the disc.

The resistance coils are of B.A. pattern. They were immersed in water, and the temperatures of the thermometers within the coil frames were read before and after each observation. A wooden box surrounded the four cans containing the coils.

The method of making the observations was the same as that described in the paper I read before the section last year (*vide* Electrical Standards Committee Report, 1893). In making them the rate of rotation of the disc is controlled with reference to a tuning-fork with riders electrically maintained in vibration, and it is measured on the tape of a Bain's electro-chemical telegraph receiver, on which the make and break of a platinum wire over a mercury-cup worked by an eccentric lever attached to the axle record the turns of the disc side-by-side with the time record of the laboratory clock.

At the same time, the observer at the galvanometer continually reverses the direction of the main current, and calls out the corresponding galvanometer readings. As a result, we have for each set of observations :

(1) The temperatures of the coils.
(2) The rate of rotation of the disc.
(3) The change of galvanometer ready consequent on reversal of the current obtained as the mean from a number of reversals proportional to the time during which the observation lasts. This time has, in the observations to be brought before the section to-day, been either one minute or three minutes—generally three.

The change of rate of rotation corresponding to a change of one division on reversal was previously determined, and hence from each set of observations the speed corresponding to the true equilibrium position could be calculated. The results are as follows, the figure in each case giving the value of the international ohm in true ohms :

July 7.—Standard coil carefully adjusted. Three minutes tapes :

·999703
·999761
·999806
·999758

Mean ·999757

July 9.—No readjustment of standard coil. One minute tapes.

999757
·999711

July 14 (afternoon).—Standard coil readjusted. Resistance coils removed and replaced. Three minutes tapes.

·999853
·999866
·999875

·999865

It is clear that in the above series the chief variations are due to changes consequent on readjustment of the standard coil and the removal and replacement of the resistance coils in their mercury-cups. Counting as independent only those of the observations before which there was readjustment of the standard coil or removal of the resistance coils from the mercury-cups, the general mean is

·99976.

The maximum variation from the mean is ·000106, or about one part in 10,000.

Assuming that the international ohm is the resistance of a column of mercury at 0deg. of one square millimetre sectional area, and 106·30cm. long, we have as a result of the above measurement that the true ohm is the resistance of a column of mercury of the same sectional area and 106·326cm. long.

The figure I arrived at in 1890 working direct on mercury was 106·307, with a probable error of ·011. The new result is, therefore, a little larger than I was prepared for. The accuracy of the result depends primarily on :

(1) The accuracy with which the resistance coils are known in terms of the international ohm.

(2) The accuracy with which their temperatures are known at the times of observation.

(3) The accuracy with which the coefficient of mutual induction of the coil and disc has been determined.

Upon the first point I can say little. Mr. Glazebrook knows better than anyone to what figure the values of the resistances may be relied on.

The effect of error in the estimation of the temperatures of the coils can be but slight. The observations have been made in two ways—viz., with one-minute tapes, the current being put on only during the time of observation, and with three-minute tapes, the current being kept on continuously, whether observations were being made or not. During the last few days of the observations the current was kept passing through the coils night and day. I have calculated the effect that would be produced on the result obtained with one-minute tapes if all the heat generated by the current were to remain in the coils—an extreme case obviously less favourable than the actual conditions. It is something less than two parts in 100,000. The smallness of the effect is due to the fact that if x is the main current, a current equal to $\frac{200}{201}x$ passes through the tenth ohm maganine coil with its small temperature coefficient, and only $\frac{1}{201}x$ through the platinum-silver coils, while the effect of underestimating the temperature of the manganine tenth ohm coil is to produce an error in the result opposite in sign to that produced by underestimating the temperature of the platinum-silver coils.

There cannot, then, in the case of the one-minute tape observations be an appreciable error due to underestimation of the temperature. But the first four sets of observations show that the results of the one-minute tape observations and the three-minute tape observations are practically the same. Hence, it follows that to the degree of accuracy aimed at our results are unaffected by errors due to underestimation of the temperature.

It remains to consider the accuracy with which the coefficient of mutual induction of the coil and disc is known. To calculate this coefficient we must know the radius of the disc and the mean radius of the coil. The circumference of the disc is a sufficiently true circle, the disc having been ground true in place. The measurement of its diameter presented no difficulty. It was determined on my Whitworth measuring machine to the ten-thousandth of an inch.

The mean radius of the coil cannot be determined with the same accuracy, but I believe that it is known to the thousandth of an inch. The coil consists of a single layer of silk-covered wire wound in a screw thread cut on a brass frame. It was measured along 18 diameters in the Whitworth machine, with the results shown in Table 1.

The measures clearly show that the coil is elliptical in section, the difference between the major and minor axis being about ·008in.. or about one part in 1,300.

In considering the possible effect of this ellipticity on the result, it must be borne in mind that the formula $R = M n$ implies that the coil is circular. The true formula is $R = 2\pi n \int_a^b \frac{r}{H} H\, d\, r$, where a and b are the distances from the centre of the disc at which the internal and external brushes are applied, and H is the magnetic force at a distance, r, from the centre when unit current is passing through the coil.

This is an unpleasant integral for an elliptical coil, and it has not yet yielded to persuasion. It is, however satisfactory to note that as in my apparatus the brush radius makes but a small angle with the minor axis (about 15deg.), I am, in so far as the ellipticity of the coil affects matters at all, underestimating the integral, and hence underestimating the international ohm. Any correction for ellipticity hereafter calculated will make the value of the international ohm deduced from any observations nearer, and not further, from the true ohm.

It is further to be noticed that the formula $R = M n$ applies only if there is exact coincidence of the axes of the disc and coil. It has been customary to consider the adjustment for centre as of secondary importance in Lorenz's method. It would be so if the formula $R = M n$ were applicable when the centres of coil and disc do not coincide, for a slight displacement only affects the coefficient of mutual induction to a secondary degree. But we are not concerned with the coefficient of mutual induction in this case. We are concerned with another integral—viz., $2\pi \int_a^b \frac{r}{H} H\, d\, r$; and the adjustment for centre is, in truth, of primary importance. Special attention should, therefore, be paid to it in designing apparatus for the absolute measurement of resistance by this method.

One other point remains to be noticed in this connection—viz., the possible effect of the difference of the temperatures of the coil and disc when measured and when in use. On calculating the correction to be applied for this cause I find it negligible.

Again, I would say, as I said last year, that the chief value of these observations consists in the proof they afford of the precision with which the absolute measurement of resistance may be made by this method. A well-constructed apparatus of the kind in a national laboratory—say the laboratory of the Board of Trade—will, I believe, prove to be the best ultimate standard of electrical resistance.

TABLE 1.

Diameter.	Measurements.
0 – 180	21·0898
10 – 190	21·0929

APPENDIX III.

Comparison of the Standard Coils Used by Prof. Jones with the Standards of the Association.

BY R. T. GLAZEBROOK.

The tenth-ohm standards of manganin wire whose value in absolute measure was determined by Prof. Jones by means of the experiments described in Appendix II., were compared with the standards of the association in the following manner : A Wheatstone's bridge was formed in which the arms were the tenth ohm to be tested, two single-ohm coils and a 10-ohm coil. If the coils had these values exactly, there would, of course, always have been a balance ; since, however, the coils were not accurately correct, there was usually a small current through the galvanometer. The balance, however, could be obtained by placing a large resistance as a shunt either to one of the one-ohm coils or to the 10-ohm coil. This resistance, which varied from 10,000 to 20,000 ohms, was taken from a good box of coils. The resistances of the 10-ohm and of the two one coils being known, that of the tenth-ohm coil could readily be found.

The four coils dipped into four mercury-cups cut in an ebonite block ; the bottoms of these cups were copper pieces some 3mm. to 4mm. thick. Binding screws screwed into these copper pieces, and rising above the mercury, serve to connect the bridge to the galvanometer and the battery.

The mercury-cups were somewhat large, about 2·5cm. in diameter, and it was found on January 16 that distinct differences could be observed by moving the tenth-ohm coils slightly, so as to bring their terminals either close to or as far as possible from the feet of the one-ohm coils which dipped into the same cups. After this date these two sets of measurements were made for each coil at each observation : in the one the terminals

Digitized by Google

of the coils in any cup were put as close together as possible; in the other the terminals of the ·1-ohm coils were placed at some distance from those of the other coil in the same cup.

Both sets of values are given in the table as a means of showing the delicacy of the observations and the error arising from this cause. The tenth-ohm coils were weighted so as to press firmly on to the copper bottoms. Now variation was produced by shifting the 10-ohm coil in its cup.

One or two Leclanchés were used in the various experiments, the coils were in water baths, and the temperature read by a standardised Kew thermometer.

The standard coils used were:

Elliott 264 = 1 + ·000312 (t − 15·45).
Nalder 3,715 = 1 + ·00026 (t − 14·95).
Elliott 289 = 10 + ·00260 (t − 15·4).

The results of the experiments are given in the following table. In the results of the experiments made after January 15 the two values given correspond to the two positions of the coil in the mercury-cup. They are included to show the magnitude of the error which may be due to the resistance of the copper bottoms of the cup.

TABLE GIVING VALUES OF NALDER No. 4,274, [C.L.C. No. 389, IN TERMS OF THE OHM STANDARDS OF THE ASSOCIATION.

Date.	Temperature (deg.).	Value of resistance.	
December 29, 1893	14·4	·100052	
January 13, 1894	15·2	·100051	
,, 15, ,,	14·8	·100056	
,, 16 ,,	15·5	·100051	·100056
,, 17 ,,	16·4	·100049	·100058
,, 27 ,,	16 9	·100057	·100066
February 20 ,,	14·1	·100036	·100041
March 17 ,,	14·1	·100045	·100046
Mean	15 2	·100050	·100054

Values of Nalder 4,275, C.L.C. 390.

Date	Temperature (deg.).	Value of resistance.	
December 29, 1893	14·6	·100059	
January 13, 1894	15	·100053	
,, 15 ,,	15	·100058	
,, 16 ,,	15·8	·100055	·100061
,, 17 ,,	16·4	·100051	·100059
,, 27 ,,	16·6	·100058	·100065
February 20 ,,	14·1	·100043	·100047
March 17 ,,	13·8	·100051	·100051
Mean	15·2	·100053	·100057

Thus the value of the coils at 15·2deg. are respectively for

C.L.C. 389, ·100050 ohm,

and for

C.L.C. 390, ·100053 ohm,

while in each case the resistance introduced by placing the contact-pieces of the tenth-ohm coils at some distance from those of the other coils is ·000004 ohm.

APPENDIX IV.

Comparison of Certain Ohm-Standards of the Board of Trade.

In the accompanying table are given the results of comparisons which I made on May 29 and 30, 1894, at the Cavendish Laboratory between the three unit coils

Elliott's No. 261,
,, No. 263,
Nalder's No. 3,876,

belonging to the Electrical Department of the Board of Trade, and the B.A. standards, Flat, F, G, and H.

No. 261 Coil.

B.A. coil.	Temp. of B.A. coil.	Temp. of B. of T. coil.	Observed value.	Chart* value.	Difference chart-observed.
Flat	12 54	12·58	·999156	·999142	− ·000014
F	12·53	12 45	064	106	+ 042
G	12·90	12 97	217	262	+ 045
No. 263 coil.					
Flat	12 50	12·53	·999136	·999140	+ ·000004
F	12 60	12·48	074	124	+ 050
G	12 80	12 98	217	271	+ 054
H	12·85	13 08	299	304	+ 005
No. 3,876 coil.					
Flat	12 60	12·45	·998808	·999,79	− ·000018
F	12·50	12·36	727	76	+ 049
G	12·70	12·23	697	74	+ 043
H	12·40	12·30	768	76	- 008

* The chart referred to, for No. 261 and No. 263 coils, is one supplied for these coils by Mr. Glazebrook, and is dated March, 1892. The chart referred to in the case of No. 3,876 was constructed from comparisons made by Nalder Bros. between it and their "master" coil, No. 3,717.

The bridge was of the Carey Foster pattern, constructed for the Department by Messrs. Nalder Bros. and Co., and the slide wire used was the one marked B, having a value of ·0000509 ohm per division.

A 100-ohm coil, Elliott's No. 291, was placed in parallel with the Board of Trade coil for each comparison; this being effected by a large mercury-in-paraffin bath.

Temperatures were measured by a mercury-in-glass thermometer, which had been standardised at Kew.

J. RENNIE.

Board of Trade Laboratory,
June, 1894.

APPENDIX V.

Table showing values of five standard coils, B.A. units, belonging to the Indian Government, as compared with Dr. Muirhead's standard at his laboratory. Standard used, Nr. 78, marked right at 15·7deg. C., taken as correct. This standard, tested April 27, 1893, against a Nr. 68 Glazebrook, gave a ratio $\frac{\text{coil}}{\text{standard}}$ of 1·00015 at 16deg. C., and 1·00018 at 15deg. 4 C.

Temperature of water, 20·2deg. C.

Number.	Marked right at.	Difference.	Correct at.
